Question 1

Not answered

Marked out of 1

A study was conducted to explore the process and outcomes of a program of occupational activities for patients with dementia. Data from observations, interviews with patients and staff, and field notes were analyzed to discover the opportunities and barriers to conducting an occupational program in a day hospital unit. The above study falls under which of the following study designs?

Select one:

- ☐ Clinical audit
- ☐ Uncontrolled trial
- ☐ Experimental
- ☐ Analytical
- ☐ Qualitative

Your answer is incorrect.

The above is an example of qualitative research. Qualitative research largely developed from social research. The important questions that can be studied qualitatively are; Why people behave the way they do How opinions and attitudes are formed How people are affected by the events that go on around them How and why cultures have developed in the way they have The differences between social groups (Retrieved from [http://libweb.surrey.ac.uk/library/skills/Introduction to Research](http://libweb.surrey.ac.uk/library/skills/Introduction%20to%20Research))

The correct answer is: Qualitative

Question 2

Not answered

Marked out of 1

Qualitative methods include all of the following except

Select one:

- ☐ Participant observation.
- ☐ Semi-structured interviews.
- ☐ Focus groups.
- ☐ Census survey.
- ☐ Discourse analysis

Your answer is incorrect.

Census survey refers to a large cross-sectional survey covering the whole, not a sample of a population. These large surveys are more suitable for quantitative data collection and synthesis; the census is not used as a qualitative research technique.

The correct answer is: Census survey.

Question 3

Not answered

Marked out of 1

In which of the following studies a qualitative approach is most appropriate?

Select one:

- ☐ A comparison of the effectiveness of tetrabenazine vs. reserpine in the treatment of tardive dyskinesia.
- ☐ A survey of number of school teachers exposed to bullying from students and the distribution of mental health problems among those teachers.
- ☐ A multicenter pragmatic naturalistic exploration of all cause discontinuation rates for antidepressants.
- ☐ An exploration of the role of the 'Community team coordinators' in the elderly community health care teams in the North East of England.
- ☐ A national postal survey of doctor's knowledge of prescribing nicotine replacement therapies.

Your answer is incorrect.

Tetrabenazine trial is clearly quantitative. National surveys of knowledge and practice are usually conducted through questionnaires which collect feeble qualitative information; these are analysed quantitatively on most occasions. The last example is a pragmatic RCT, far from a qualitative study. Some situations where qualitative research is useful are, 1. When exploring the nature of the problem to be studied; i.e. before planning quantitative research 2. To generate hypothesis based on observations made. 3. Investigating anomalies or oddities observed during clinical practice 4. Examining policy implementation 5. Collating service users/ carers/ staff views.

The correct answer is: An exploration of the role of the 'Community team coordinators' in the elderly community health care teams in the North East of England.

Question 4

Not answered

Marked out of 1

Which of the following is generally a feature of qualitative but not quantitative research?

Select one:

- ☐ Testing hypothesis
- ☐ Purposeful sampling
- ☐ Controlled interventions
- ☐ Estimation of causative factors
- ☐ Deductive approach

Your answer is incorrect.

Testing a hypothesis, random sampling, controlled interventions or exploration of aetiology and generalising inferences (deductive approach) are used in quantitative research. Qualitative research uses a purposeful sample, often includes outliers and anomalies, in order to generate a theory or hypothesis.

The correct answer is: Purposeful sampling

Question 5

Not answered

Marked out of 1

In grounded theory method of qualitative research, the term theoretical saturation is used to describe which of the following?

Select one:

- ☐ Point at which the research hypothesis is fully formed
- ☐ Point at which the research is stopped
- ☐ Point at which no new categories can be developed from the available data
- ☐ Process of checking validity of information using various sources of data
- ☐ Process of testing new categories using fresh data

Your answer is incorrect.

The grounded theory refers to a technique of generating theories/categories using qualitative methods. In this technique, i. Initially, a constant comparison of the collected data takes place in different stages of the data collection. ii. From these comparisons, categories are generated until nothing new is revealed, i.e. the point of theoretical saturation is reached. iii. Later these categories are tested by collecting further fresh data on the basis of the new categories made - this is called theoretical sampling.

The correct answer is: Point at which no new categories can be developed from the available data

Question 6

Not answered

Marked out of 1

Which of the following methods is the most appropriate to explore the experience and meaning of stigma by schizophrenia patients, their relatives, and health professionals?

Select one:

- ☐ A case control study with two control groups
- ☐ A well constructed single self report questionnaire
- ☐ Participant observation for all three groups individually
- ☐ Postal survey with rewards for returning the questionnaire
- ☐ Focus groups

Your answer is incorrect.

Conducting interviews in a group format with some predetermined structure for such groups, in order to provide a focus for discussion, is called 'focus groups' (Kitzinger, 1995). Focus groups usually contain a small number of members selected giving views on the chosen topic; the discussion here is semi-structured guided by key points. These are useful in gathering opinions of service users and providers. Postal surveys and self-report questionnaires do not generate much data needed for adequate understanding of 'life experiences'.

The correct answer is: Focus groups

Question 7

Not answered

Marked out of 1

In which of the following research methods the clear cut demarcation between researcher" and "researched" may not be so apparent?"

Select one:

- ☐ Case series
- ☐ Grounded theory
- ☐ Action research
- ☐ Ethnography
- ☐ Phenomenology

Your answer is incorrect.

PAR (or simply action research) involves individuals and groups researching their own personal beings, socio-cultural settings and experiences. The clear cut demarcation between and 'researcher' and the 'researched' that is found in other types of research may not be so apparent in action research. For example, a PAR study may involve researchers working with carers of schizophrenia patients to identify which family or environmental situations provide substantial challenges to the service users. Meyer, J. (2000) Qualitative research in health care. Using qualitative methods in health related action research. British Medical Journal, 320, 178-181

The correct answer is: Action research

Question 8

Not answered

Marked out of 1

In a research interview, the interviewer does not follow any order but frames the questions on the basis of the interviewee's previous response. Which of the following style is he following?

Select one:

- ☐ Semistructured interview
- ☐ Motivational interview
- ☐ Unstructured interview
- ☐ Structured interview
- ☐ Projective interview

Your answer is incorrect.

In structured interviews, a tight schedule of questions may be used with an intention to elicit one of the few limited range of responses, similar to a questionnaire. Semi-structured interviews (sometimes referred to as focused interviews) involve a series of open-ended questions based on the topic areas the researcher wants to cover. Though there is a schedule of topics to cover, the exact way questions are phrased is not premeditated or dictated by a list. Unstructured interviews are also referred to as 'in-depth' interviews where the interviewer has some limited number of topics in his mind but does not follow any order and frames the questions on the basis of the interviewee's previous response

The correct answer is: Unstructured interview

Question 9

Not answered

Marked out of 1

A researcher organises focus groups to explore the experience of being admitted to an intensive psychiatric care ward. All of the following will increase the usefulness of the study method except

Select one:

- ☐ More than one focus group is used in the actual project
- ☐ Having a good degree of group interaction
- ☐ Having a predetermined topic to discuss at the group
- ☐ All members of the groups have the common experience of being inpatients in the ward
- ☐ Each group has around 24 to 36 subjects only

Your answer is incorrect.

Focus groups are very useful when limited resources prevent individual interviews. They are used when the studied individuals share a common factor where collecting views of several of them may be useful; these factors should be important to the topic of investigation. If group interaction may allow greater insights to be developed, focus groups may be used. Members must be usually 6 - 10; it is not a good idea to have just one group for the whole research - many small groups must be included in the research

The correct answer is: Each group has around 24 to 36 subjects only

Question 10

Not answered

Marked out of 1

Which of the following terms describe the procedure for producing a written version of a qualitative research interview?

Select one:

- ☐ Transcribing
- ☐ Discourse analysis
- ☐ Latent analysis
- ☐ Triangulation
- ☐ Coding

Your answer is incorrect.

Data collection process in qualitative research includes transcribing. Transcribing is the procedure for producing a written version of the interview. It is a full 'script' of the interview. Transcribing is a time-consuming process. The estimated ratio of time required for transcribing interviews is about 5:1 (i.e. a 10 minutes interview may need 50 minutes to be transcribed).

The correct answer is: Transcribing

Question 11

Not answered

Marked out of 1

Which of the following clinical questions is better suited to qualitative rather than quantitative research methods?

Select one:

- ☐ A study to measure quality of life in people with Alzheimer's disease.
- ☐ A study to measure psychiatric symptoms after a head injury
- ☐ A study of the costs per unit of 'patient utility' in a randomized controlled trial
- ☐ A study to assess the attitudes of people with borderline personality disorder to their diagnosis
- ☐ A study detailing the functional outcomes of people treated with Cognitive Behavioural Therapy

Your answer is incorrect.

The quality of life is often established using standardised questionnaires that test the degree of presumed life quality in samples. Such questionnaires yield quantitative data for statistical analysis. Patient utility costs are studied using quantitative economic analyses. Study of attitudes of borderline patients towards their diagnosis is a good example of qualitative design.

The correct answer is: A study to assess the attitudes of people with borderline personality disorder to their diagnosis

Question 12

Not answered

Marked out of 1

Theoretical sampling is associated with

Select one:

- ☐ Intuition to answer a question
- ☐ Convenience sample
- ☐ Randomisation
- ☐ Using non-emerging categories for further research
- ☐ Developing a theory for further research

Your answer is incorrect.

Theoretical sampling is associated with the generation of a new theory for further research. It uses categories that emerge during a qualitative interview (grounded theory process) to construct the theory. It is not an intuitive method; it does not involve randomisation or picking up of a convenient sample.

The correct answer is: Developing a theory for further research

Question 13

Not answered

Marked out of 1

Qualitative methods are useful in all except:

Select one:

- ☐ Evaluating treatment response
- ☐ Hypothesis generation
- ☐ Finding out user views.
- ☐ Investigating anomalous results
- ☐ Exploring barriers to policy implementation

Your answer is incorrect.

Quantitative methods are better suited for evaluating treatment response.

The correct answer is: Evaluating treatment response

Question **14**

Not answered

Marked out of 1

Qualitative methods include all except:

Select one:

- ☐ Ethnography
- ☐ Case-control study
- ☐ Semi-structured interviews
- ☐ Participant observation
- ☐ Focus groups

Your answer is incorrect.

A case-control study is a quantitative research method.

The correct answer is: Case-control study

Question 15

Not answered

Marked out of 1

Which of the following can be used to demonstrate the validity of a qualitative study?

Select one:

- ☐ Exclusiveness of research question
- ☐ Duration of time spent on research
- ☐ Non systematic methods of enquiry
- ☐ Reflexivity in reporting results
- ☐ The significance value derived for primary outcome

Your answer is incorrect.

Reflexivity means sensitivity to the ways in which the researcher and the research process have shaped the collected data, including the role of prior assumptions and experience, which can influence the results. The degree of reflexivity in a qualitative study is used as a method of assessing the validity of the study. Other methods include triangulation, respondent checking and deviant case analysis. Brown, C and Lloyd, K (2001). Qualitative methods in psychiatric research. Adv Psych Treatment, 7, 350-356.

The correct answer is: Reflexivity in reporting results

Question 16

Not answered

Marked out of 1

Reflexivity involves:

Select one:

- ☐ Awareness of the patient as a positioned observer in research
- ☐ Knowledge of the socialist theories
- ☐ Consideration of the impact of the presence of the disease on data collected
- ☐ Refusing generated theory if any deviant case is noted
- ☐ Recognition of the researcher's preconceptions and their influence on interpretation and analysis

Your answer is incorrect.

Reflexivity means sensitivity to the ways in which the researcher and the research process have shaped the collected data. It includes recognition of the researcher's preconceptions and their influence on interpretation and analysis. Brown, C and Lloyd, K (2001). Qualitative methods in psychiatric research. Adv Psych Treatment, 7, 350-356.

The correct answer is: Recognition of the researcher's preconceptions and their influence on interpretation and analysis

Question 17

Not answered

Marked out of 1

Which one of the following techniques is useful in validating data from qualitative studies?

Select one:

- ☐ Sensitivity analysis
- ☐ Concealed allocation
- ☐ Boot strapping
- ☐ Triangulation
- ☐ Minimisation

Your answer is incorrect.

Triangulation is a qualitative research technique in which a researcher compares the findings of different methods and the perspectives of different people or groups to help produce a more comprehensive set of findings; this is not the same as inter-rater reliability, and does not necessarily require more than one researcher

The correct answer is: Triangulation

Question 18

Not answered

Marked out of 1

In qualitative studies, semi-structured interviews are often chosen over other forms of interviews. This is because

Select one:

- ☐ Higher validity of semi-structured technique
- ☐ Good balance between resource limitations and amount of data collected
- ☐ Easy accessibility of established interview schedules
- ☐ Inexpensive nature of this technique
- ☐ Exploratory nature of the interview

Your answer is incorrect.

The strengths of the semistructured interview methodology include its ability to balance the need for acquiring good quality data that is required to investigate complex behaviors and motivations with the limited time available to researchers in the field. In addition, semi-structured interviews have better response rates than a questionnaire survey; are particularly useful when discussing sensitive issues as they enable the researcher to explore new phenomenon as well as enquire about expected phenomena; achieve good comparability by ensuring that all items are answered by each participant; ensure that the responses are not influenced by group dynamics or assistance from others; are more informative when there are large variations within the sample groups, regardless of the factors that bring about those variations. In the presence of such variability, a structured interview might not pick the underlying differences while an unstructured interview may lose focus and fail to answer the primary research question. Leech, B. (2002). Asking questions: Techniques for semistructured interviews. Political Science and Politics. 35(4):665-668.

The correct answer is: Good balance between resource limitations and amount of data collected

Question 19

Not answered

Marked out of 1

Which of the following research methods is commonly used in qualitative research?

Select one:

- ☐ Self report questionnaires
- ☐ Functional analysis of behaviour
- ☐ Ethnographic approach
- ☐ Surveys
- ☐ Structured interviews

Your answer is incorrect.

Ethnography involves immersing oneself in a particular social group.

The correct answer is: Ethnographic approach

Question **20**

Not answered

Marked out of 1

You are preparing a study involving a focus group of mental health occupation therapists, exploring their views of memory clinic assessments. Which of the following is the most important factor to consider for reliability?

Select one:

- ☐ Ensuring the occupational therapists are a representative sample
- ☐ Ensuring all the occupational therapists have the same amount of experience with memory clinics
- ☐ Using more than one researcher to facilitate the focus group
- ☐ Facilitating the group so that there is not too much discussion amongst participants
- ☐ Using more than one researcher to code the data

Your answer is incorrect.

Reliability in a qualitative study can be improved by triangulation and member checking.

The correct answer is: Using more than one researcher to code the data

Question **21**

Not answered

Marked out of 1

Theoretical sampling is associated with

Select one:

- ☐ Using non-emerging categories for further research
- ☐ Developing a theory for further research
- ☐ Convenience sample
- ☐ Randomisation
- ☐ Intuition to answer a question

Your answer is incorrect.

Theoretical sampling is often considered to be the hallmark of grounded theory methodology. It involves the use of emerging categories using an iterative process to refine the theory developed from the data.

The correct answer is: Developing a theory for further research

Question **22**

Not answered

Marked out of 1

Qualitative methods are useful in all except:

Select one:

- ☐ Evaluating treatment response
- ☐ Exploring barriers to policy implementation
- ☐ Hypothesis generation
- ☐ Finding out user views.
- ☐ Investigating anomalous results

Your answer is incorrect.

To evaluate a treatment response, we must resort to quantitative methods.

The correct answer is: Evaluating treatment response

Question 23

Not answered

Marked out of 1

Woolf et al., BMJ 2008; 337. 27 year 3 medical students and 25 clinical teachers at a London medical school, selected for required ethnicity and sex, participated in a study that used semistructured one to one interviews and focus groups. Ethnic stereotypes of UK medical students were explored in the context of academic underachievement of medical students from ethnic minorities. Overall, 26 of 40 clinical teachers agreed to be interviewed (65%), 12 did not answer, and two declined: one was too busy and one did not give a reason. Of the 49 students invited to participate, 21 agreed to be interviewed (43%). Twelve interviews took place—six with white students and six with students from ethnic minorities. Five of the students were men and seven were women. High achievers were more likely to attend the focus groups than low achievers (19.3% v 9.0% of those invited). The Pakistani/Bangladeshi lower achieving group had to be abandoned as a result of non-attendance. Data were analysed using the theory of stereotype threat (a psychological phenomenon thought to negatively affect the performance of people from ethnic minorities in educational contexts) and the constant comparative method. Throughout the analysis the interpretation was compared with the verbatim data. Opposite examples were sought and used to refine the analysis. Participants believed the student-teacher relationship was vital for clinical learning. Teachers had strong perceptions about "good" clinical students (interactive, keen, respectful), and some described being aggressive towards students whom they perceived as quiet, unmotivated, and unwilling. Students had equally strong perceptions about "good" clinical teachers (encouraging, interested, interactive, non-aggressive). Students and teachers had concordant and well developed perceptions of the "typical" Asian clinical medical student who was considered over-reliant on books, poor at communicating with patients, too quiet during clinical teaching sessions, and unmotivated owing to being pushed into studying medicine by ambitious parents. Stereotypes of the "typical" white student were less well developed: autonomous, confident, and outgoing team player. Direct discrimination was not reported. This investigation suggested that the Asian clinical medical students may be more likely than white students to be perceived stereotypically and negatively, which may reduce their learning by jeopardising their relationships with teachers. The existence of a negative stereotype about their group also raises the possibility that underperformance of medical students from ethnic minorities may be partly due to stereotype threat. The sex, ethnicity, and age of the interviewer (British female, white) may have affected participants' discussion of certain topics. The investigator perceived that white clinical teachers who had positive views about white female medical students and rather more negative views about Asian or male medical students felt comfortable discussing these views with her in a way that they may not have had she been an Asian medical student. What type of study has been conducted?

Select one:

- ☐ Opinion survey
- ☐ Qualitative study
- ☐ Cohort study

- ☐ Cross-sectional survey
- ☐ Case series

Your answer is incorrect.

This is a qualitative study. Note the terms – 'semistructured', 'focus groups' and 'constant comparative' method.

The correct answer is: Qualitative study

Question 24

Not answered

Marked out of 1

Woolf et al., BMJ 2008; 337. 27 year 3 medical students and 25 clinical teachers at a London medical school, selected for required ethnicity and sex, participated in a study that used semistructured one to one interviews and focus groups. Ethnic stereotypes of UK medical students were explored in the context of academic underachievement of medical students from ethnic minorities. The existence of a negative stereotype about their group also raises the possibility that underperformance of medical students from ethnic minorities may be partly due to stereotype threat. The sex, ethnicity, and age of the interviewer (British female, white) may have affected participants' discussion of certain topics. The investigator perceived that white clinical teachers who had positive views about white female medical students and rather more negative views about Asian or male medical students felt comfortable discussing these views with her in a way that they may not have had she been an Asian medical student. What type of sampling has been used?

Select one:

- ☐ Volunteer sampling
- ☐ Snowball sampling
- ☐ Convenience sampling

- ☐ Purposive sampling
- ☐ Random sampling

Your answer is incorrect.

Purposive sampling has been used here as the subjects were selected for certain required characteristics, typical of qualitative studies.

The correct answer is: Purposive sampling

Question 25

Not answered

Marked out of 1

Woolf et al., BMJ 2008; 337. 27 year 3 medical students and 25 clinical teachers at a London medical school, selected for required ethnicity and sex, participated in a study that used semistructured one to one interviews and focus groups. Ethnic stereotypes of UK medical students were explored in the context of academic underachievement of medical students from ethnic minorities. Five of the students were men and seven were women. High achievers were more likely to attend the focus groups than low achievers (19.3% v 9.0% of those invited). The Pakistani/Bangladeshi lower achieving group had to be abandoned as a result of non-attendance. Data were analysed using the theory of stereotype threat (a psychological phenomenon thought to negatively affect the performance of people from ethnic minorities in educational contexts) and the constant comparative method. Throughout the analysis the interpretation was compared with the verbatim data. Opposite examples were sought and used to refine the analysis. Participants believed the student-teacher relationship was vital for clinical learning. Teachers had strong perceptions about "good" clinical students (interactive, keen, respectful), and some described being aggressive towards students whom they perceived as quiet, unmotivated, and unwilling. Students had equally strong perceptions about "good" clinical teachers (encouraging, interested, interactive, non-aggressive). Students and teachers had concordant and well developed perceptions of the "typical" Asian clinical medical student who was considered over-reliant on books, poor at communicating with patients, too quiet during clinical teaching sessions, and unmotivated owing to being pushed into studying medicine by ambitious parents. Stereotypes of the "typical" white student were less well developed: autonomous, confident, and outgoing team player. Direct discrimination was not reported. This investigation suggested that the Asian clinical medical students may be more likely than white students to be perceived stereotypically and negatively, which may reduce their learning by jeopardising their relationships with teachers. The existence of a negative stereotype about their group also raises the possibility that underperformance of medical students from ethnic minorities may be partly due to stereotype threat. The sex, ethnicity, and age of the interviewer (British female, white) may have affected participants' discussion of certain topics. The investigator perceived that white clinical teachers who had positive views about white female medical students and rather more negative views about Asian or male medical students felt comfortable discussing these views with her in a way that they may not have had she been an Asian medical student. The aim of this study is

Select one:

- ☐ To establish the degree of racial discrimination in UK medical schools
- ☐ To explore the causes of underachievement of medical students from ethnic minority
- ☐ To explore the quality of teacher-student relationship in UK medical schools

- ☐ To explore ethnic stereotypes of UK medical students
- ☐ To characterize the qualities of Asian medical students

Your answer is incorrect.

The aim of this study was to explore ethnic stereotypes in a UK medical school.

The correct answer is: To explore ethnic stereotypes of UK medical students

Question 26

Not answered

Marked out of 1

Woolf et al., BMJ 2008; 337. 27 year 3 medical students and 25 clinical teachers at a London medical school, selected for required ethnicity and sex, participated in a study that used semistructured one to one interviews and focus groups. Ethnic stereotypes of UK medical students were explored in the context of academic underachievement of medical students from ethnic minorities. Overall, 26 of 40 clinical teachers agreed to be interviewed (65%), 12 did not answer, and two declined: one was too busy and one did not give a reason. Of the 49 students invited to participate, 21 agreed to be interviewed (43%). Twelve interviews took place—six with white students and six with students from ethnic minorities. Five of the students were men and seven were women. High achievers were more likely to attend the focus groups than low achievers (19.3% v 9.0% of those invited). The Pakistani/Bangladeshi lower achieving group had to be abandoned as a result of non-attendance. Data were analysed using the theory of stereotype threat (a psychological phenomenon thought to negatively affect the performance of people from ethnic minorities in educational contexts) and the constant comparative method. Throughout the analysis the interpretation was compared with the verbatim data. Opposite examples were sought and used to refine the analysis. Participants believed the student-teacher relationship was vital for clinical learning. Teachers had strong perceptions about "good" clinical students (interactive, keen, respectful), and some described being aggressive towards students whom they perceived as quiet, unmotivated, and unwilling. Students had equally strong perceptions about "good" clinical teachers (encouraging, interested, interactive, non-aggressive). Students and teachers had concordant and well developed perceptions of the "typical" Asian clinical medical student who was considered over-reliant on books, poor at communicating with patients, too quiet during clinical teaching sessions, and unmotivated owing to being pushed into studying medicine by ambitious parents. Stereotypes of the "typical" white student were less well developed: autonomous, confident, and outgoing team player. Direct discrimination was not reported. This investigation suggested that the Asian clinical medical students may be more likely than white students to be perceived stereotypically and negatively, which may reduce their learning by jeopardising their relationships with teachers. The existence of a negative stereotype about their group also raises the possibility that underperformance of medical students from ethnic minorities may be partly due to stereotype threat. The sex, ethnicity, and age of the interviewer (British female, white) may have affected participants' discussion of certain topics. The investigator perceived that white clinical teachers who had positive views about white female medical students and rather more negative views about Asian or male medical students felt comfortable discussing these views with her in a way that they may not have had she been an Asian medical student. Which of the following can be considered as an inherent problem in this study?

Select one:

- ☐ Exclusion bias
- ☐ Lack of randomisation
- ☐ Sampling bias

- ☐ Generalisability
- ☐ Measurement bias

Your answer is incorrect.

Generalisability is a problem inherent in all qualitative studies. The low participation rate in the focus groups and the relatively low numbers of non-white clinical teachers may have introduced a systematic bias., but this is not an exclusion bias or sampling bias.

The correct answer is: Generalisability

Question 27

Not answered

Marked out of 1

Woolf et al., BMJ 2008; 337. 27 year 3 medical students and 25 clinical teachers at a London medical school, selected for required ethnicity and sex, participated in a study that used semistructured one to one interviews and focus groups. Ethnic stereotypes of UK medical students were explored in the context of academic underachievement of medical students from ethnic minorities. Overall, 26 of 40 clinical teachers agreed to be interviewed (65%), 12 did not answer, and two declined: one was too busy and one did not give a reason. Of the 49 students invited to participate, 21 agreed to be interviewed (43%). Twelve interviews took place—six with white students and six with students from ethnic minorities. Five of the students were men and seven were women. High achievers were more likely to attend the focus groups than low achievers (19.3% v 9.0% of those invited). The Pakistani/Bangladeshi lower achieving group had to be abandoned as a result of non-attendance. Data were analysed using the theory of stereotype threat (a psychological phenomenon thought to negatively affect the performance of people from ethnic minorities in educational contexts) and the constant comparative method. Throughout the analysis the interpretation was compared with the verbatim data. Opposite examples were sought and used to refine the analysis. Participants believed the student-teacher relationship was vital for clinical learning. Teachers had strong perceptions about "good" clinical students (interactive, keen, respectful), and some described being aggressive towards students whom they perceived as quiet, unmotivated, and unwilling. Students had equally strong perceptions about "good" clinical teachers (encouraging, interested, interactive, non-aggressive). Students and teachers had concordant and well developed perceptions of the "typical" Asian clinical medical student who was considered over-reliant on books, poor at communicating with patients, too quiet during clinical teaching sessions, and unmotivated owing to being pushed into studying medicine by ambitious parents. Stereotypes of the "typical" white student were less well developed: autonomous, confident, and outgoing team player. Direct discrimination was not reported. This investigation suggested that the Asian clinical medical students may be more likely than white students to be perceived stereotypically and negatively, which may reduce their learning by jeopardising their relationships with teachers. The existence of a negative stereotype about their group also raises the possibility that underperformance of medical students from ethnic minorities may be partly due to stereotype threat. The sex, ethnicity, and age of the interviewer (British female, white) may have affected participants' discussion of certain topics. The investigator perceived that white clinical teachers who had positive views about white female medical students and rather more negative views about Asian or male medical students felt comfortable discussing these views with her in a way that they may not have had she been an Asian medical student. To achieve triangulation, which of the following has been carried out in this study?

Select one:

- ☐ Both Whites and Asians were included
- ☐ The students were kept blind from the investigator's ethnicity
- ☐ Both students and teachers were interviewed

- ☐ Both females and males were studied
- ☐ The investigator was kept blind from the students' ethnicity

Your answer is incorrect.

Both students and teachers were interviewed, which provided triangulation of the results, and the data were analysed by two researchers with different backgrounds—one non-clinical psychology researcher and one clinical teacher and medical educationalist, which improved validity and reliability.

The correct answer is: Both students and teachers were interviewed

Question 28

Not answered

Marked out of 1

Woolf et al., BMJ 2008; 337. 27 year 3 medical students and 25 clinical teachers at a London medical school, selected for required ethnicity and sex, participated in a study that used semistructured one to one interviews and focus groups. Ethnic stereotypes of UK medical students were explored in the context of academic underachievement of medical students from ethnic minorities. Overall, 26 of 40 clinical teachers agreed to be interviewed (65%), 12 did not answer, and two declined: one was too busy and one did not give a reason. Of the 49 students invited to participate, 21 agreed to be interviewed (43%). Twelve interviews took place—six with white students and six with students from ethnic minorities. Five of the students were men and seven were women. High achievers were more likely to attend the focus groups than low achievers (19.3% v 9.0% of those invited). The Pakistani/Bangladeshi lower achieving group had to be abandoned as a result of non-attendance. Data were analysed using the theory of stereotype threat (a psychological phenomenon thought to negatively affect the performance of people from ethnic minorities in educational contexts) and the constant comparative method. Throughout the analysis the interpretation was compared with the verbatim data. Opposite examples were sought and used to refine the analysis. Participants believed the student-teacher relationship was vital for clinical learning. Teachers had strong perceptions about "good" clinical students (interactive, keen, respectful), and some described being aggressive towards students whom they perceived as quiet, unmotivated, and unwilling. Students had equally strong perceptions about "good" clinical teachers (encouraging, interested, interactive, non-aggressive). Students and teachers had concordant and well developed perceptions of the "typical" Asian clinical medical student who was considered over-reliant on books, poor at communicating with patients, too quiet during clinical teaching sessions, and unmotivated owing to being pushed into studying medicine by ambitious parents. Stereotypes of the "typical" white student were less well developed: autonomous, confident, and outgoing team player. Direct discrimination was not reported. This investigation suggested that the Asian clinical medical students may be more likely than white students to be perceived stereotypically and negatively, which may reduce their learning by jeopardising their relationships with teachers. The existence of a negative stereotype about their group also raises the possibility that underperformance of medical students from ethnic minorities may be partly due to stereotype threat. The sex, ethnicity, and age of the interviewer (British female, white) may have affected participants' discussion of certain topics. The investigator perceived that white clinical teachers who had positive views about white female medical students and rather more negative views about Asian or male medical students felt comfortable discussing these views with her in a way that they may not have had she been an Asian medical student. The sex, ethnicity, and age of the interviewer (British female, white) may have affected participants' discussion of certain topics. This awareness is called

Select one:

- ☐ Metacognition
- ☐ Resonance
- ☐ Member checking

- ☐ Reflexivity
- ☐ Research insight

Your answer is incorrect.

Reflexivity is the process of "benign introspection" which involves thinking about how the researcher's own experiences may have influenced the data collection and interpretation in a qualitative study.

The correct answer is: Reflexivity

Woolf et al., BMJ 2008; 337. 27 year 3 medical students and 25 clinical teachers at a London medical school, selected for required ethnicity and sex, participated in a study that used semistructured one to one interviews and focus groups. Ethnic stereotypes of UK medical students were explored in the context of academic underachievement of medical students from ethnic minorities. Overall, 26 of 40 clinical teachers agreed to be interviewed (65%), 12 did not answer, and two declined: one was too busy and one did not give a reason. Of the 49 students invited to participate, 21 agreed to be interviewed (43%). Twelve interviews took place—six with white students and six with students from ethnic minorities. Five of the students were men and seven were women. High achievers were more likely to attend the focus groups than low achievers (19.3% v 9.0% of those invited). The Pakistani/Bangladeshi lower achieving group had to be abandoned as a result of non-attendance. Data were analysed using the theory of stereotype threat (a psychological phenomenon thought to negatively affect the performance of people from ethnic minorities in educational contexts) and the constant comparative method. Throughout the analysis the interpretation was compared with the verbatim data. Opposite examples were sought and used to refine the analysis. Participants believed the student-teacher relationship was vital for clinical learning. Teachers had strong perceptions about "good" clinical students (interactive, keen, respectful), and some described being aggressive towards students whom they perceived as quiet, unmotivated, and unwilling. Students had equally strong perceptions about "good" clinical teachers (encouraging, interested, interactive, non-aggressive). Students and teachers had concordant and well developed perceptions of the "typical" Asian clinical medical student who was considered over-reliant on books, poor at communicating with patients, too quiet during clinical teaching sessions, and unmotivated owing to being pushed into studying medicine by ambitious parents. Stereotypes of the "typical" white student were less well developed: autonomous, confident, and outgoing team player. Direct discrimination was not reported. This investigation suggested that the Asian clinical medical students may be more likely than white students to be perceived stereotypically and negatively, which may reduce their learning by jeopardising their relationships with teachers. The existence of a negative stereotype about their group also raises the possibility that underperformance of medical students from ethnic minorities may be partly due to stereotype threat. The sex, ethnicity, and age of the interviewer (British female, white) may have affected participants' discussion of certain topics. The investigator perceived that white clinical teachers who had positive views about white female medical students and rather more negative views about Asian or male medical students felt comfortable discussing these views with her in a way that they may not have had she been an Asian medical student. A constant comparative approach has been used for data-analysis. One of the advantages of this approach is that

Select one:

- ☐ Confirmatory hypotheses were tested
- ☐ The emerging categories were refined in a flexible manner
- ☐ The study became more cost-effective

- ☐ It was possible to meaningfully organize the data
- ☐ A small sample size was sufficient

Your answer is incorrect.

All data were analysed using stereotype threat as a theoretical framework, but an iterative approach (constant comparison) ensured that these theories were refined as the study progressed. The strong theoretical underpinnings of the data analysis were useful in organizing the data meaningfully

The correct answer is: The emerging categories were refined in a flexible manner

Question 30

Five of the students were men and seven were women. High achievers were more likely to attend the focus groups than low achievers (19.3% v 9.0% of those invited). The Pakistani/Bangladeshi lower achieving group had to be abandoned as a result of non-attendance. Data were analysed using the theory of stereotype threat (a psychological phenomenon thought to negatively affect the performance of people from ethnic minorities in educational contexts) and the constant comparative method. Throughout the analysis the interpretation was compared with the verbatim data. Opposite examples were sought and used to refine the analysis. Participants believed the student-teacher relationship was vital for clinical learning. Teachers had strong perceptions about "good" clinical students (interactive, keen, respectful), and some described being aggressive towards students whom they perceived as quiet, unmotivated, and unwilling. Students had equally strong perceptions about "good" clinical teachers (encouraging, interested, interactive, non-aggressive). Students and teachers had concordant and well developed perceptions of the "typical" Asian clinical medical student who was considered over-reliant on books, poor at communicating with patients, too quiet during clinical teaching sessions, and unmotivated owing to being pushed into studying medicine by ambitious parents. Stereotypes of the "typical" white student were less well developed: autonomous, confident, and outgoing team player. Direct discrimination was not reported. This investigation suggested that the Asian clinical medical students may be more likely than white students to be perceived stereotypically and negatively, which may reduce their learning by jeopardising their relationships with teachers. The existence of a negative stereotype about their group also raises the possibility that underperformance of medical students from ethnic minorities may be partly due to stereotype threat. The sex, ethnicity, and age of the interviewer (British female, white) may have affected participants' discussion of certain topics. The investigator perceived that white clinical teachers who had positive views about white female medical students and rather more negative views about Asian or male medical students felt comfortable discussing these views with her in a way that they may not have had she been an Asian medical student. The conclusions of the study are

Select one:

- ☐ Typical 'Asian' student stereotypes are well formed
- ☐ Asian medical students may show significant underachievement in London medical schools
- ☐ The student-teacher relationship is not an important factor in determining the quality of learning.

- ☐ Typical 'White' student stereotype does not exist in medical schools
- ☐ Students believed that to foster relationships it was important to find out about teacher's individual educational capabilities

Your answer is incorrect.

Qualitative studies often conclude by posing new questions that require further examination. The present study suggests that Asian medical students may show significant underachievement in London medical schools, which may be related to the stereotypes perceived.

The correct answer is: Asian medical students may show significant underachievement in London medical schools

Question **31**

Not answered

Marked out of 1

Which of the following research techniques used during a qualitative study can inform the number of participants necessary for a given sample?

Select one:

- ☐ Triangulation
- ☐ Reflexivity
- ☐ Power calculation
- ☐ Resonance
- ☐ Saturation

Your answer is incorrect.

Saturation is a research technique that is used during a qualitative study to inform the number of participants necessary for a given sample; data are analysed concurrently with data collection, and the sample is said to be saturated (so data collection can cease) when new themes stop emerging from the data that have already been gathered. Resonance is a term employed to describe the extent that findings from qualitative research "resonate" with (have meaning for) readers/audiences; broader resonance allows researchers more confidence with respect to the applicability of their research to other settings

The correct answer is: Saturation
