Question **1**

Not answered

Marked out of 5.00

Human development

Which different stages of development below correspond to the appropriate age in the list?

Margaret Mahler's phase of symbiosis	Choose...
Concrete operational stage of Piaget's cognitive model	Choose...
Intimacy vs. isolation stage of Erik Erikson's psychosocial development	Choose...
Kohler's stage of preconventional morality	Choose...
Phallic stage of Freud's developmental model	Choose...

Choose...
2-6 months
0-10 years
7-12 years
Middle adulthood
1-2 years
3-5 years
6-36 months
Old age
Young adulthood
0-1 years

Explanation:

Margaret Mahler proposed a theory to describe how young children acquire a sense of identity separate from that of their mothers'. During symbiosis (age 2-5 months), mother-infant is perceived as a single fused entity.

According to Piaget, the stage of concrete operations lasts from about 7 to 11 years of age. In this period, children operate and act on the concrete, real, and perceivable world of objects and events.

Erik Erikson created an original and highly influential theory of psychological development and crisis occurring in periods that extended across the entire life cycle. Stage 6 takes place from about 21 years to about 40 years (young adulthood). Its focus is intimacy versus isolation

Lawrence Kohlberg integrated Jean Piaget's concepts and described multiple stages of moral development within three significant levels of morality. The first level is pre-conventional morality (up to age 10 years), in which punishment and obedience are the determining factors.

Freud's phallic stage begins sometime during year 3 and continues until approximately the end of year 5. The phallic stage lays the foundation for gender identity and serves to integrate residues from the previous stages into a predominantly genital-sexual orientation.

Ref: Boland R, Verduin M. Kaplan and Sadock's Synopsis of Psychiatry, 12th Edition. 2022. pp. 892-893, 902, 1008, 1062-1063, 1071-1075.

The correct answer is: Margaret Mahler's phase of symbiosis → 2-6 months, Concrete operational stage of Piaget's cognitive model → 7-12 years, Intimacy vs. isolation stage of Erik Erikson's psychosocial development → Young adulthood, Kohler's stage of preconventional morality → 0-10 years, Phallic stage of Freud's developmental model → 3-5 years

Question **2**

Not answered

Marked out of 6.00

Attachment Behaviour

For each of the following attachment behaviour, choose the most appropriate age of presentation from the list provided;

Infant orientates visually without discrimination	Choose...
Infant shows preferential orientation towards selected persons	Choose...
Onset of preferential attachment and stranger anxiety	Choose...
Formation of goal-directed partnership between child and caregiver	Choose...
Lessening of attachment behaviour and attachment figure can be substituted.	Choose...
Attachment behaviour typically peaks during this period	Choose...

Choose...
School age
7-9 months of age
12- 18 months of age
9-36 months
6 to 12 months of age
First few months
36-48 months of age
5-7 months of age

Phases of attachment:Preattachment phase (birth to 8 or 12 weeks)- babies orient to their mothers.

Indiscriminate attachment phase (attachment in making - 8 to 12 weeks to 6 months)- Allows strangers to handle, infants become attached to one or more persons in the environment.

Clear-cut attachment (6 through 24 months)- Preferential attachment, separation anxiety, object permanence, stranger anxiety. At a later part, weakened stranger anxiety; other attachment figures may also present.

Attachment behaviour peaks between 12-18 months. After 25 months, the mother figure is seen as independent.

The correct answer is: Infant orientates visually without discrimination → First few months, Infant shows preferential orientation towards selected persons → 5-7 months of age, Onset of preferential attachment and stranger anxiety → 7-9 months of age, Formation of goal-directed partnership between child and caregiver → 9-36 months, Lessening of attachment behaviour and attachment figure can be substituted. → School age, Attachment behaviour typically peaks during this period → 12- 18 months of age

Question **3**

Not answered

Marked out of 6.00

Language development

Identify the age of language development for each of the descriptions given below

The baby speaks 18-40 words	Choose...
First social smile	Choose...
Repetitive babbling	Choose...
Correct use of grammar	Choose...
A child can use the words 'mama' and 'dada'	Choose...
Starts to differentiate familiar and unfamiliar faces	Choose...

Choose...
24 months
7-11 years
36 months
60 months
48 months
Six weeks.
18 months
3 months
9 months
12-18 years
12 months

At age 4-6 weeks the baby smiles at the mother (social smile - 6 weeks); can recognise mum's face amidst other faces and shows a preference for visually attending to human faces. At 9-10 months, the baby babbles tunefully. At one year of age, the child can speak one or two words. At 18 months of age, the child can use many intelligible words, up to 40 in some.

The correct answer is: The baby speaks 18-40 words → 18 months, First social smile → Six weeks., Repetitive babbling → 9 months, Correct use of grammar → 48 months, A child can use the words 'mama' and 'dada' → 12 months, Starts to differentiate familiar and unfamiliar faces → 3 months

Question **4**

Not answered

Marked out of 6.00

Developmental fears

For each of the following types of fear, identify the age at which they appear?

Fear of imaginary creatures — Choose...

Fear of animals — Choose...

Fear of the dark — Choose...

Fear of illness and death — Choose...

Fear of loud noises — Choose...

Fear of falling — Choose...

Choose...
Age 5 and above
Teenage onwards
No particular age trend
Age 3
Age 4 to 5
Later childhood
Infancy

Developmental fears: Fear characteristic of infancy include fear of loud noises, fear of falling, fear of strange objects and strange people.Fear of animals-age 3, Fear of the dark-age 4 or 5, Fear of imaginary creatures - 5 plus, Fear of open spaces arise in later childhood or adult life, Fears that arise in late childhood include fear of sex and fear of open spaces. From teenage onwards, fears of failure, illness and death are seen. Fears that show no particular age trend include fear of snakes and natural events such as storms.

The correct answer is: Fear of imaginary creatures → Age 5 and above, Fear of animals → Age 3, Fear of the dark → Age 4 to 5, Fear of illness and death → Teenage onwards, Fear of loud noises → Infancy, Fear of falling → Infancy

Question **5**

Not answered

Marked out of 3.00

Features of language acquisition

Identify the age of language development for the situations given below

Telegraphic speech, grammatically pairs words with vocabulary more than 240 words — Choose...

Language akin to adult speech — Choose...

Early comprehension of syntax — Choose...

Choose...
Six weeks
3 months
36 months
60 months
9 months
18 months
24 months
7-11 years
48 months
12 months
12-18 years

Explanation:

By 24 months, children use three-word telegraphic utterances (‘all gone ball’, ‘me go now’) and have an increased vocabulary of up to 270 words.

By 55-60 months, children have reached the level of true communication (akin to adult speech). Their speech is 100% intelligible. They use language to tell stories, share ideas, and discuss alternatives.

Early comprehension of syntax occurs by 36 months, when children use real sentences with grammatical function words (can, will, the, a).

Ref: Boland R, Verduin M. Kaplan and Sadock's Synopsis of Psychiatry, 12th Edition. 2022. p. 889.

The correct answer is: Telegraphic speech, grammatically pairs words with vocabulary more than 240 words → 24 months, Language akin to adult speech → 60 months, Early comprehension of syntax → 36 months

Question **6**

Not answered

Marked out of 5.00

Flag question

Perceptual development

Choose the most mature perceptual function achieved by the child at the following ages from the list above

Six months: Choose...

Two months: Choose...

Four months: Choose...

One month: Choose...

At birth: Choose...

Choose...
Possess perceptual constancy
Able to fix objects and can have a fixed focus at about 2 cm
Vision is the most developed sense at birth
Can have colour vision and accommodation
Prefers three-dimensional rather than two-dimensional representations of a face
Can differentiate faces
The acuity if newborn is around 10/300
Accurate acuity of vision
Able to track and scan objects

The foetus responds to bright light flashed on the abdominal wall of the 20-week with changes in heart rate and position. Vision is the least developed sense at birth; the acuity if newborn is around 20/300. At birth, infants can track and scan objects, can discriminate levels of brightness, able to fix objects, fixed focus at about 20 cm, figure-ground discrimination. At 1month, the infant differentiates faces from other stimuli with a preference shown for face-like complex stimuli. At two months, the infant possesses depth perception, prefers three-dimensional rather than two-dimensional representations of a face. At four months, colour vision and accommodation are noted to develop and at six months an accurate acuity (6:6) is achieved in most infants.

The correct answer is: Six months → Accurate acuity of vision, Two months → Prefers three-dimensional rather than two-dimensional representations of a face, Four months → Can have colour vision and accommodation, One month → Can differentiate faces, At birth → Able to track and scan objects

Question **7**

Not answered

Marked out of 3.00

Flag question

Phases of Attachment

With the descriptions given below, identify the phases of attachment according to various attachment theories;

A 10 weeks old baby orientates to her mother: Choose...

A 5-month-old baby allows strangers to handle and become

Choose... t review

Proximity seeking
Indiscriminate attachment
Pre-attachment phase
Insecure attachment
Re-orientation
Clear cut attachment
Anxious resistant
Independent attachment

attached to mother, sister and grandmother at home — Choose...

A 2-year-old child shows preferential attachment to mother but also attaches to the father — Choose...

Explanation:

In the first attachment phase, sometimes called the pre-attachment stage, (birth to 8-12 weeks), babies orient to their mothers, follow them with their eyes over a 180-degree range, and turn toward and move rhythmically with their mothers' voices. In the second phase, sometimes called attachment in the making (8-12 weeks to 6 months), infants become attached to one or more persons in the environment (indiscriminate attachment). In the third phase, sometimes called clear-cut attachment (6 through 24 months), infants cry and show other signs of distress when separated from the mother or other caregiver such as the father. In the fourth phase (25 months and beyond), the mother figure is seen as independent, and a more complex relationship between the mother and the child develops.

Ref: Boland R, Verduin M. Kaplan and Sadock's Synopsis of Psychiatry, 12th Edition. 2022. p. 1011.

The correct answer is: A 10 weeks old baby orientates to her mother → Pre-attachment phase, A 5-month-old baby allows strangers to handle and become attached to mother, sister and grandmother at home → Indiscriminate attachment, A 2-year-old child shows preferential attachment to mother but also attaches to the father → Clear cut attachment

Question **8**

Not answered

Marked out of 9.00

Irregular biorhythms
Slow changes in mood
Negative emotional display
High degree of physical energy
Readily adapt to changes
Gradually adapt to changes
Low activity levels
Fiery response to changes
Regular biorhythms
Positive emotional display

HiY Development CXEMI008

Temperament Clusters

For each of the three behavioural styles given below, identify their characteristic temperamental dimensions from list above;(Identify three correct answers for each)

1. Easy child (Three choices)

2. Slow to warm up child (Three choices)

3. Difficult child (Three choices)

Explanation:

Thomas & Chess conducted the New York Longitudinal Study (1986). It was a thirty-year (initially six years) longitudinal study of 138 children, observing childhood temperaments. It employed parental interviews to ascertain temperamental dimensions. Three behavioural styles were identified. According to Chess and Thomas, children with an 'easy' temperament (40% of children) are characterised by biorhythm regularity, positive response approaches to new stimuli, rapid adaptability to change, and mild or moderate predominantly positive intensity of mood. Children with 'slow-to-warm-up' temperament (15% of children) display initial withdrawal to new situations combined with slow adaptability and mild intensity. 'Difficult' children (10% of children) display predominantly negative

withdrawal responses to new stimuli, slow adaptability to change, and intense expression of predominantly negative mood. Their biological functions are irregular.

Ref: Hertzig ME. Temperament: Then and now. The Journal of nervous and mental disease. 2012 Aug 1;200(8):659-63.

The correct answer is:

Easy child (Three choices) - High degree of physical energy, Readily adapt to changes, Regular biorhythms

Slow to warm up child (Three choices) - Slow changes in mood, Low activity levels, Gradually adapt to changes

Difficult child (Three choices) - Irregular biorhythms, Negative emotional display, Fiery response to changes

Question **9**

Marked out of 3.00

Strange situation experiment

Based on the behaviour of the child in strange situation experiment, identify the type of attachment pattern exhibited.

The child displays strong initial proximity seeking followed by high avoidance. When the mother returns the child gets frightened, distressed and frozen. — Choose...

The child appears normally interested in caregiver, and explores busily. There was minimal distress at separation and on reunion the child ignored the caregiver and focused on the environment. — Choose...

The child shows a high level of distress on separation from the mother. On re-union, they approach their mother angrily, resist comforting, pushing their mother away and take a long time to settle down. — Choose...

Choose...
Secure attachment
Preattachment
Indiscriminate attachment
Anaclitic depression
Resistant/ambivalent attachment
Avoidant/anxious attachment
Disorganised attachment
Deprived attachment

Explanation:

Mary Ainsworth devised the Strange Situation procedure with 12- to 18-month infants, which categorised infant-parent relationships. The procedure involves separations and reunions with caregivers and observes response. Bizarre, confused, or contradictory behaviour is characteristic of disorganised attachment behaviour. It is often associated with maltreatment or parental trauma. In insecure-avoidant attachment, the child seems unconcerned at separation or reunion. It is associated with unresponsive parenting. In insecure-ambivalent attachment, the child shows distress on separation and resistance to comfort on caregiver return. It is associated with inconsistent parenting. In secure attachment, the child is distressed by separation but can quickly be soothed on reunion with the caregiver. It is associated with attuned parenting.

Ref: Semple D, Smyth R. Oxford handbook of psychiatry. Oxford university press; 2019 Jul 30. pp. 658-659.

The correct answer is: The child displays strong initial proximity seeking followed by high avoidance. When the mother returns the child gets frightened, distressed and frozen. → Disorganised attachment, The child appears normally interested in caregiver, and explores busily. There was minimal distress at separation and on reunion the child ignored the caregiver and focused on the environment. → Avoidant/anxious attachment, The child shows a high level of distress on separation from the mother. On re-union, they approach their mother angrily, resist comforting, pushing their mother away and take a long time to settle down. → Resistant/ambivalent attachment

Adult Attachment Interview

With the descriptions given below, identify the type of attachment behaviour described in Adult Attachment Interviews

The subject provides spontaneous and coherent answers in a non-defensive manner with sufficient elaboration and is able to talk freely about positive or negative experiences in childhood. — Choose...

The subject often minimises his or her experiences, often gives brief answers or "'I don't remember" statements and does not use colourful metaphors during the discourse. — Choose...

The subject who had insecure but enmeshed attachment shows an outpouring of emotion with a lengthy discussion of childhood memories and is often distressed, angry and tearful. — Choose...

Explanation:

The Adult Attachment Interview (AAI) – an hour-long, semi-structured interview about individuals' experiences with their primary caregivers during childhood – is a widely used measure in both developmental science and developmental psychology research for assessing adults' attachment representations. The standard system for coding the AAI recommends classifying individuals categorically as having an autonomous, dismissing, preoccupied/entangled, or unresolved/disorganised attachment state of mind.

Individuals are classified as having an autonomous/secure state of mind if they coherently discuss their experiences with their caregivers, regardless of whether those experiences are described as positive or not. Individuals who appear to avoid discussing their childhood caregiving histories by idealising their caregivers or by claiming to have difficulty remembering their experiences are classified as having a dismissing state of mind. Individuals who become emotionally overwhelmed when discussing their childhood caregiving experiences, as indicated by anger or passivity, are classified as having a preoccupied or entangled state of mind.

Ref: Raby KL et al. The latent structure of the adult attachment interview: Large sample evidence from the collaboration on attachment transmission synthesis. Development and Psychopathology. 2020 Oct 19;1:13.

The correct answer is: The subject provides spontaneous and coherent answers in a non-defensive manner with sufficient elaboration and is able to talk freely about positive or negative experiences in childhood. → Autonomous, The subject often minimises his or her experiences, often gives brief answers or "'I don't remember" statements and does not use colourful metaphors during the discourse. → Dismissing, The subject who had insecure but enmeshed attachment shows an outpouring of emotion with a lengthy discussion of childhood memories and is often distressed, angry and tearful. → Entangled

Separation Individuation Theory

With the features given below, identify the phase in Margaret-Mahler's separation-individuation theory

A 1-month old newborn baby spends most time in sleep as if the intrauterine aloofness continues — Choose...

An 18-month old child has alternating drives to be autonomous and dependent; the child can explore alone but — Choose...

Choose...
Practicing sub-phase
Symbiosis phase
Rapprochement sub-phase
Formal operational phase
Object constancy sub-phase
Differentiation sub-phase
Pre-operational phase
Normal autism

requires comfort and reassurance on the mother's return

A three-year-old child understands that the mother will not be lost if temporarily away; is hence able to function independently — Choose...

Explanation:

Margaret Mahler described the development of a sense of identity in young children, independent of their mothers'. This is called the separation-individuation theory, and the stages are proposed to be universal in all children.

Stage	Age	Description: Mahler's separation-individuation
Normal autism	Birth-2 months	Periods of sleep outweigh periods of arousal Reminiscent of intrauterine life
Symbiosis	2-5 months	Developing perceptual abilities enables infant to distinguish inner from outer world Mother-infant perceived as a single fused entity
Differentiation/ Hatching	5-10 months	Progressive neurological development and increased alertness Infant's attention drawn away from self to the outer world Physical and psychological distinctiveness from mother gradually appreciated
Practicing	10-18 months	Ability to move autonomously increases child's exploration of outer world
Rapprochement	18-24 months	Child slowly realises helplessness and dependence Need for independence alternates with need for closeness Child moves away from mother and comes back for reassurance
Object constancy	2-5 years	Child gradually comprehends and is reassured by permanence of mother and other important people, even when not in their presence

Adapted from Kaplan and Sadock's Synopsis of Psychiatry, 12th Edition, 2022. pp. 892-893.

SPMM COURSE

Ref: Boland R, Verduin M. Kaplan and Sadock's Synopsis of Psychiatry, 12th Edition. 2022. pp. 892-893.

The correct answer is: A 1-month old newborn baby spends most time in sleep as if the intrauterine aloofness continues → Normal autism, An 18-month old child has alternating drives to be autonomous and dependent; the child can explore alone but requires comfort and reassurance on the mother's return → Rapprochement sub-phase, A three-year-old child understands that the mother will not be lost if temporarily away; is hence able to function independently → Object constancy sub-phase

Question **12**

Marked out of 3.00

Erikson's psychosocial stages

For each of the descriptions below choose the most appropriate developmental stage from Erikson's descriptions using the list above

Choose...
Generativity vs. Stagnation
Trust vs. Mistrust
Intellectuality vs Deficit
Guilt vs Shame
Autonomy vs. Shame
Identity vs. Confusion
Autonomy vs Despair
Integrity vs Despair
Intimacy vs Stagnation
Happiness vs Despondency

A 3-year-old boy insists that he wants to open a door himself despite not having the strength to do so. He cries when his father attempts to help him. — Choose...

A 50-year-old woman works hard to save up money to help her children leave home. — Choose...

A 72-year-old retired academic psychiatrist mostly travels and reads but spends some time in limited private legal work related to psychiatry. — Choose...

Explanation:

Erik Erikson created an original and highly influential theory of psychological development and crisis occurring in periods that extended across the entire life cycle. Stage 2 takes place from about 18 months to about 3 years. Its focus is autonomy versus shame and doubt. Erikson believed that this stage "becomes decisive for the ratio between loving goodwill and hateful self-insistence, between cooperation and willfulness, and between self-expression and compulsive self-restraint or meek compliance". Where that ratio is favourable, the child develops an appropriate sense of autonomy and the capacity to 'have and to hold'; where it is unfavourable, doubt and shame with undermine free will. Stage 7 takes place from about 40 years to about 60 years. Its focus is generativity versus stagnation. Generativity encompasses a protective concern for generations and social institutions, as well as productivity and creativity. The last and 8th stage – integrity vs despair – takes place from about 60 years until death. Erikson defined integrity as "the acceptance of one's one and only life cycle and of the persons who have become significant to it as something that had to be and that, by necessity, permitted of no substitutions."

Ref: Boland R, Verduin M. Kaplan and Sadock's Synopsis of Psychiatry, 12th Edition. 2022. pp. 1071-1075.

The correct answer is: A 3-year-old boy insists that he wants to open a door himself despite not having the strength to do so. He cries when his father attempts to help him. → Autonomy vs. Shame, A 50-year-old woman works hard to save up money to help her children leave home. → Generativity vs. Stagnation, A 72-year-old retired academic psychiatrist mostly travels and reads but spends some time in limited private legal work related to psychiatry. → Integrity vs Despair

Question **13**

Not answered

Marked out of 4.00

Piaget's experiments

For each of the following Piaget's stage of cognitive development, identify the types of experiments used to demonstrate them.

Choose...
Visual cliff test
Strange situation test
Rouge Test
Classification of objects according to rules
Heinz Dilemma
Mountain tasks
Pendulum experiment
Bobo Doll experiment
Touching the dot experiment
Peek-a-boo games
Piaget's experiments
One-dollar/20-dollar experiment

Sensorimotor stage of cognitive development	Choose...
Pre-operational stage of cognitive development	Choose...
Formal operational stage of cognitive development	Choose...
Concrete operational stage of cognitive development	Choose...

Explanation:

In the sensorimotor stage (birth to 2 years), infants learn to differentiate themselves from the world. They also become able to maintain a mental image of an object, even when it is not visible (object permanence). It is during this stage that children play peek-a-boo.

Egocentrism is a term given a technical meaning by psychologist Jean Piaget to denote a cognitive state in which a child in the pre-operational stage of development comprehends the world only from its own point of view and is unaware that other people's points of view differ from their own. It implies a failure to differentiate subjective from objective aspects of experience, and it therefore imposes an unconscious personal bias on cognition. The classic demonstration of it is Piaget's three mountains task, in which a child sits in front of a table-top model of three mountains and is asked how the scene would look to a doll viewing it from a different angle. Most children in the pre-operational stage consistently describe the doll's viewpoint as being the same as their own.

According to Piaget, the stage of concrete operations lasts from about 7 to 11 years of age. In this

period, children operate and act on the concrete, real, and perceivable world of objects and events. Children in this stage begin to use limited logical thought processes and can serialise, order, and group things into classes based on common characteristics. Children can reason and follow the rules and regulations.

According to Piaget, the stage of formal operations lasts from about 11 years of age through the end of adolescence. The stage is so named because young persons' thinking operates in a formal, highly logical, systematic, and symbolic manner. Hypotheticodeductive thinking, the highest organisation of cognition, enables people to make a hypothesis or proposition and to test it against reality. In the pendulum experiment, the participant is asked to work out what governs the speed of an object swinging on a piece of string. The ability to systematically examine variables (length, weight, force of drop, height of drop) is evidence of hypothetico-deductive reasoning.

Ref: Boland R, Verduin M. Kaplan and Sadock's Synopsis of Psychiatry, 12th Edition. 2022. pp. 1007-1009.

Colman AM. Oxford Dictionary of Psychology, 4th Edition. 2015. p. 237.

The correct answer is: Sensorimotor stage of cognitive development → Peek-a-boo games, Pre-operational stage of cognitive development → Mountain tasks, Formal operational stage of cognitive development → Pendulum experiment, Concrete operational stage of cognitive development → Classification of objects according to rules

Question **14**

Not answered

Marked out of 4.00

Play and development

Identify the type of play using the descriptions given below

The child plays with a rattle by shaking it	Choose...
The child speaks to his grandpa over a toy phone	Choose...
A 7-year-old child enjoys playing board games with children of similar age	Choose...
A child in a doctor's waiting room invites another child to share the plastic toy given to him by his mother	Choose...

Choose...
Sensorimotor play
Parallel play
Rule governed play
Symbolic play
Emotional play
Co-operative play
Solitary play

Explanation:

Play is the engagement of activity for enjoyment and recreation rather than for any set purpose. It is an expected, normal process in children. Play starts 'primitively' as **sensorimotor play** from 1-2 years with an exploration of properties and functions of objects (e.g. shaking a rattle). Between the ages of 1 and 2, imaginative or pretend play replaces sensorimotor play. **Pretend play** is a direct imitation of ordinary activities. Pretend play extends to **symbolic play**, which is the use of one object for another (e.g. a toy phone). Between 2 and 3 years, children commonly engage in **parallel play**, **solitary play** alongside another child with no interaction between them. By age 3, play is often **associative**, that is, playing with the same toys in pairs or small groups, but still with no real interaction among them. By age 4, children are usually able to share and engage in **cooperative play**. Real interactions and taking turns become possible. In middle childhood, peer play evolves into games involving structure, rules, and competition (**rule-governed play).**

Ref: Boland R, Verduin M. Kaplan and Sadock's Synopsis of Psychiatry, 12th Edition. 2022. p. 895.

The correct answer is: The child plays with a rattle by shaking it → Sensorimotor play, The child speaks to his grandpa over a toy phone → Symbolic play, A 7-year-old child enjoys playing board games with children of similar age → Rule governed play, A child in a doctor's waiting room invites another child to share the plastic toy given to him by his mother → Co-operative play

Question **15**

Marked out of 6.00

Choose...
Genital phase
Latency phase
Conventional phase
Phallic phase
Rectal phase
Potency phase
Oral phase
Anal phase
Lateral phase

Freud's psychosexual stages

For each of the characteristics given below, identify the phase at which they are attained according to Freud's theory of psychosexual development

Establishment of mature object relationships	Choose...
Castration anxiety and resolution of oedipal complex	Choose...
Strive for control	Choose...
Establishment of trust	Choose...
Socialization and interest in peers	Choose...
True self-identity develops during this stage	Choose...

Explanation:

Sigmund Freud proposed psychosexual stages that include the oral stage (birth to 1-11/2 years), anal stage (11/2- 3 years), phallic stage (3-5 years), latency stage (5-6 years to 12 years) and genital stage (12 years onwards).

Successful resolution of the oral phase results in capacities to give and to and receive from others without excessive dependence or envy and to rely on others with a sense of trust as well as a sense of self-reliance and self-trust.

The anal phase is marked by greater striving for independence and separation from dependence on and control of parents.

In the phallic phase, the influence of castration anxiety and penis envy, defences against them, and patterns of identification are primary determinants of the development of human character. Resolution of the oedipal conflict gives rise to internal structural capacities for regulation of drive impulses and their direction to constructive ends.

The latency stage is characterised by energetic learning and play activities, exploring the environment, and becoming more proficient in dealing with the world of things and peers.

Primary objectives of the genital stage are the ultimate separation from dependence on and attachment to parents and establishment of mature object relations. Related are the achievement of a mature sense of personal identity and acceptance and integration of adult roles and functions.

Ref: Boland R, Verduin M. Kaplan and Sadock's Synopsis of Psychiatry, 12th Edition. 2022. pp. 1062-1063.

The correct answer is: Establishment of mature object relationships → Genital phase, Castration anxiety and resolution of oedipal complex → Phallic phase, Strive for control → Anal phase, Establishment of trust → Oral phase, Socialization and interest in peers → Latency phase, True self-identity develops during this stage → Genital phase

Question **16**

Not answered

Marked out of 6.00

Developmental stages and virtues

For each of Erik Erikson's psychosocial stages of development, identify the associated virtue from the list provided:

Choose...
Fidelity
Will
Anticipation
Experimentation
Love
Competence
Care
Hope
Wisdom
Purpose

Identity vs. Role Confusion	Choose...
Autonomy vs. Shame and Doubt	Choose...
Integrity vs. Despair	Choose...
Generativity vs. Stagnation	Choose...
Trust vs. Mistrust	Choose...
Intimacy vs. Isolation	Choose...

Explanation:

Erik Erikson proposed eight developmental, psychosocial stages. The associated virtues in 8 stages are hope, will, purpose, competence, fidelity, love, care and wisdom.

Erikson's Psychosocial Stage	Age	Associated Virtue	Enduring Aspects of Identity Formation
Trust vs. mistrust	Birth-18 months	Hope	Temporal perspective vs. time confusion
Autonomy vs. shame and doubt	18 months-3 years	Will	Self-certainty vs. self-consciousness
Initiative vs. guilt	3-5 years	Purpose	Role experimentation vs. role fixation
Industry vs. inferiority	5-13 years	Competence	Apprenticeship vs. work paralysis
Identity vs. role confusion	13-21 years	Fidelity	Identity vs. identity confusion
Intimacy vs. isolation	21-40 years	Love	Self-abandonment vs. self-absorption
Generativity vs. stagnation	40-60 years	Care	Leadership and followership vs. abdication of responsibility
Integrity vs. despair	60 years-death	Wisdom	Ideological commitment vs. confusion of values

Adapted from Kaplan and Sadock's Synopsis of Psychiatry, 12th Edition, 2022. pp. 1073-1075.

SPMM COURSE

Ref: Boland R, Verduin M. Kaplan and Sadock's Synopsis of Psychiatry, 12th Edition. 2022. pp. 1073-1075.

The correct answer is: Identity vs. Role Confusion → Fidelity, Autonomy vs. Shame and Doubt → Will, Integrity vs. Despair → Wisdom, Generativity vs. Stagnation → Care, Trust vs. Mistrust → Hope, Intimacy vs. Isolation → Love

Question **17**

Flag question

Theories of development

Choose two appropriate options from the given list for each of the following developmental theorists

Lawrence Kohlberg	Choose...
Sigmund Freud	Choose...
Erik Erikson	Choose...

Choose...
Stagnation, Self-actualisation
Anal stage, Genital stage
Autonomy - inferiority, Intellectuality - deficit
Autonomy - shame, Integrity - despair
Attachment in the making, Clear-cut attachment
Symbiotic stage, Autistic stage
Sensorimotor, Preoperational
Good boy - Good girl, Authority orientation

Margaret Mahler — Choose...

Explanation:

Lawrence Kohlberg integrated Jean Piaget's concepts and described multiple stages of moral development within three significant levels of morality. The first level is pre-conventional morality, in which punishment and obedience are the determining factors. The second level is morality of conventional role-conformity, in which children try to conform to gain approval and maintain good relationships with others and are also guided by rigid codes of 'law and order' (authority orientation). The third and highest level is the morality of self-accepted moral principles (post-conventional), in which children voluntarily comply with rules based on a concept of universal ethical principles and make exceptions to rules in certain circumstances.

Freud proposed that psychosexual development occurs during infancy and childhood through a sequence of libidinal stages, including the oral, anal, phallic, latency, and genital stages

Erik Erikson created an original and highly influential theory of psychological development and crisis occurring in periods that extended across the entire life cycle. Stage 2 takes place from about 18 months to about 3 years. Its focus is autonomy versus shame and doubt. The last and 8th stage – integrity vs despair – takes place from about 60 years until death.

Margaret Mahler proposed a theory to describe how young children acquire a sense of identity separate from that of their mothers'. The first stage is 'normal autism' from birth to 2 months. In this stage, periods of sleep outweigh periods of arousal in a state reminiscent of intrauterine life. During symbiosis (age 2-5 months), mother-infant is perceived as a single fused entity.

Ref: Boland R, Verduin M. Kaplan and Sadock's Synopsis of Psychiatry, 12th Edition. 2022. pp. 892-893, 902, 1071-1075.

Colman AM. Oxford Dictionary of Psychology, 4th Edition. 2015. pp. 167, 619-620.

The correct answer is: Lawrence Kohlberg → Good boy - Good girl, Authority orientation, Sigmund Freud → Anal stage, Genital stage, Erik Erikson → Autonomy - shame, Integrity - despair, Margaret Mahler → Symbiotic stage, Autistic stage

Question **18**

Not answered

Marked out of 3.00

Choose...
Bonding
Monotropy
Polytropy
Rapprochement
Disorganised attachment
Authoritative parenting
Insecure attachment
Authoritarian parenting
Imprinting
Normal autism
Permissive parenting
Ambivalent attachment
Avoidant attachment
Individuation

Child development

Choose ONE developmental concept that best fits each of the scenarios below:

A 20-months-old child cries whenever her mother, father or childminder bid goodbye to her when leaving. — Choose...

A 14-months-old child has an indifferent attitude to mother leaving the room or entering the room. He keeps playing indifferent to the mother'92s presence but shows signs of distress when alone. — Choose...

A 28-months-old child can stay alone for prolonged periods but still seeks reassurance, expresses her joy and runs to get a hug on the return of her mother from work. — Choose...

This child has more than one attachment figure - this is called as polytropy. In the avoidant pattern of attachment, the child has an indifferent attitude towards mother's presence and feels similarly comfortable both with the stranger and the mother. Rapprochement refers to the third subphase during the separation-individuation process described by Mahler. The child, despite learning new skills, remains anxious regarding the loss of the love of caregiver when they are away. This is evident when

the child runs to hug the mother on her return from regular absence (e.g. from work).

The correct answer is: A 20-months-old child cries whenever her mother, father or childminder bid goodbye to her when leaving. → Polytropy, A 14-months-old child has an indifferent attitude to mother leaving the room or entering the room. He keeps playing indifferent to the mother'92s presence but shows signs of distress when alone. → Avoidant attachment, A 28-months-old child can stay alone for prolonged periods but still seeks reassurance, expresses her joy and runs to get a hug on the return of her mother from work. → Rapprochement

Question **19**

1 month
5 years
3 years
3 months
6 months
6 years
9months
7 years
2 years

Developmental age

Choose ONE representative age that best fits each of the given scenarios:

A child can localise sound source and discriminates smile response. Choose...

A child builds six cube towers and can speak in two-word sentences with no propositions. Choose...

A child can copy a cross and a circle, but cannot copy a triangle or diamond. He is also toilet trained for both bladder and bowel control. Choose...

A child can copy a circle, build nine cubes tower and speak in sentences. Choose...

At three months a child can babble to some extent, can discriminate mother's smile and localize the source of a sound. At two years of age, a child can build six cube towers; can use words in a meaningful way as if sending a telegraph (two words with no conjunctions). At age four a cross can be copied, but not a triangle or diamond. At age three a child can go up stairs 1 foot per step and downstairs 2 feet per step; can copy a circle, and build a tower of 9 cubes.

The correct answer is: A child can localise sound source and discriminates smile response. → 3 months, A child builds six cube towers and can speak in two-word sentences with no propositions. → 2 years, A child can copy a cross and a circle, but cannot copy a triangle or diamond. He is also toilet trained for both bladder and bowel control. → 4 years, A child can copy a circle, build nine cubes tower and speak in sentences. → 3 years

Question **20**

Not answered

Marked out of 3.00

Choose...
Detachment
Indiscriminate attachment
Emotionality
Separation anxiety
Disenchantment
Proximity seeking
Re-orientation
Secure base effect

Attachment related behaviours

For each of the descriptions given below, identify the type of attachment behaviour from the list

A 3-year-old child was taken to a toddlers' group by his mother, to whom he is primarily attached. With his mother being present, he attempts to move around, explore and interact with others in the room. Choose...

An 18-month-old baby became tearful and distressed when one of the health visitors took her away from her mum for an examination. Choose...

A 12 month old baby tends to follow and remain in close contact with her mother all the time. Choose...

Explanation:

Mary Ainsworth proposed that attachment serves to reduce anxiety. What she called the '**secure base effect'** enables children to move away from attachment figures and to explore the environment.

Separation anxiety is the response of an infant who is isolated or separated from its mother or caretaker. It is most common at 10-18 months of age and generally disappears by the end of the third year. It is usually expressed with tearfulness or irritability.

Attachment can be defined as the emotional tone between children and their caregivers and is evidenced by a child's seeking and clinging to the caregiving person, usually the mother. This **proximity-seeking** promotes closeness to the desired person.

Ref: Boland R, Verduin M. Kaplan and Sadock's Synopsis of Psychiatry, 12th Edition. 2022. pp. 892, 1011-1013.

The correct answer is: A 3-year-old child was taken to a toddlers' group by his mother, to whom he is primarily attached. With his mother being present, he attempts to move around, explore and interact with others in the room. → Secure base effect, An 18-month-old baby became tearful and distressed when one of the health visitors took her away from her mum for an examination. → Separation anxiety, A 12 month old baby tends to follow and remain in close contact with her mother all the time. → Proximity seeking

Question **21**

Not answered

Marked out of 4.00

Developmental anxieties

For the given situations below, identify the type of anxiety exhibited.

This normally occurs around the age of 7-9 months during a child's development — Choose...

This occurs when the mother is recognised as an independent object — Choose...

This has been described to occur especially in girls during phallic stage — Choose...

This is the most mature form of anxiety characterised by prohibitive conflicts — Choose...

Choose...
Fear of object loss
Separation anxiety
Signal anxiety
Stranger anxiety
Disintegration
Phobic anxiety
Annihilation anxiety
Generalised anxiety
Superego anxiety

Explanation:

Stranger anxiety appears at about 8 months as an anxiety response to someone other than the caregiver. At the approach of a stranger, infants cry and cling to their mothers.

Separation anxiety is the response of an infant who is isolated or separated from its mother or caretaker. It is most common at 10-18 months of age and generally disappears by the end of the third year. It is usually expressed with tearfulness or irritability.

During the oedipal (phallic) psychosexual stage, girls are most concerned about losing the love of the most crucial figure/object in their lives, their mother. Boys are primarily anxious about bodily injury or castration.

After resolving the oedipal conflict, a more mature form of anxiety occurs, often termed 'superego anxiety'. This latency-age concern involves the fear that internalised parental representations, contained in the superego, will cease to love, or will angrily punish, the child.

Ref: Boland R, Verduin M. Kaplan and Sadock's Synopsis of Psychiatry, 12th Edition. 2022. pp. 892, 1012-1013, 1065.

The correct answer is: This normally occurs around the age of 7-9 months during a child's development → Stranger anxiety, This occurs when the mother is recognised as an independent object → Separation anxiety, This has been described to occur especially in girls during phallic stage → Fear of object loss, This is the most mature form of anxiety characterised by prohibitive conflicts → Superego anxiety

Question **22**

Marked out of 8.00

Trust vs. mistrust
Autonomy vs. shame
Anal phase
Sensorimotor stage
Pre-operational stage
Concrete operational stage
Deductive reasoning
Oral phase
Initiative vs. guilt
Industry vs. inferiority
Phallic stage
Genital stage

HiY Development CXEMI022

Psychosexual and cognitive development

For each of the following ages, choose options that correspond to the most appropriate psychosexual and cognitive development from the above list

1. A 9-month old child. (Choose three)

2. A 4-year old child. (Choose three)

3. A 17-year old child. (Choose two)

Explanation: Erik Erikson proposed 8 developmental psychosocial stages. It includes Basic Trust vs Mistrust (birth to 12-18 months), Autonomy vs Shame (18 months to 3 years), Initiative vs. Guilt (3-6 years), Industry vs Inferiority (6-12 years), Identity vs Role Confusion (adolescence), Intimacy vs Isolation (young adulthood), Generativity vs. stagnation (middle adulthood), Ego integrity vs despair (late adulthood). Jean Piaget proposed four important stages of cognitive development. It includes sensorimotor stage (0 to 2 years), pre-operational stage (2-7 years), concrete operational stage (7-11 years) and formal operational stage (more than 11 years). Hypothetico-deductive reasoning is a feature of the formal operational stage, which develops in a proportion of children after the age of 12. Sigmund Freud proposed psychosexual stages that includes oral phase (birth to 1-11/2 years), anal phase (11/2- 3 years), phallic stage (3-5 years), Latency stage (5-6 years to 12 years) and genital stage (12 years onwards).

The correct answer is:

A 9-month old child. (Choose THREE)- Trust vs. mistrust,Sensorimotor stage, Oral phase,

A 4-year old child. (Choose THREE) - Pre-operational stage, Initiative vs. guilt, Phallic stage,

A 17-year old child. (Choose TWO) - Deductive reasoning, Genital stage

Question **23**

Not answered

Pre-operational
Concrete operational
Reward orientation stage
Universal ethics stage
Depressive position
Oral stage
Formal operational
Anal stage
Paranoid/schizoid position
Phallic stage
Latent stage

Psychoanalytic concepts of development

Choose the most relevant stage related to each clinical scenario described below.

A patient has repeated obsessive thoughts regarding dirt and contamination. His anxiety is only partially reduced by repeated washing and checking hands for germs. According to the psychoanalytic theory, at which stage is he fixated?

Choose...

A patient indulges in excessive drinking to bring pleasure. He neglects other sources of leisure activities completely. According to the psychoanalytic theory, at which stage is he fixated?

Choose...

At this developmental stage, projection of both bad and good

impulses onto the maternal object is seen. This is followed by splitting of the external world into good and bad. The child is unable to unify these elements into one.

Choose...

Explanation:

Orderliness, obstinacy, stubbornness, willfulness, frugality, and parsimony are features of **anal character**. Anal characteristics and defenses are typically seen in **obsessive-compulsive neuroses.**

Excessive **oral gratifications or deprivation** can result in libidinal fixations contributing to pathological traits. According to classic psychoanalytic theories, substance abuse such as alcohol abuse may be a manifestation of **oral regression** (i.e., dependency).

Melanie Klein **viewed projection and introjection** as the primary defensive operations in the first months of life. Infants project derivatives of the death instinct into the mother and then fear attack from the 'bad mother'. This anxiety is intimately associated with the **paranoid-schizoid position**, infants' mode of organising experience in which all aspects of infant and mother are **split** into **good and bad elements.**

Ref: Boland R, Verduin M. Kaplan and Sadock's Synopsis of Psychiatry, 12th Edition. 2022. pp. 275, 1062, 1083.

The correct answer is: A patient has repeated obsessive thoughts regarding dirt and contamination. His anxiety is only partially reduced by repeated washing and checking hands for germs. According to the psychoanalytic theory, at which stage is he fixated? → Anal stage, A patient indulges in excessive drinking to bring pleasure. He neglects other sources of leisure activities completely. According to the psychoanalytic theory, at which stage is he fixated? → Oral stage, At this developmental stage, projection of both bad and good impulses onto the maternal object is seen. This is followed by splitting of the external world into good and bad. The child is unable to unify these elements into one. → Paranoid/schizoid position

Question **24**

Marked out of 7.00

Proponents of developmental concepts

From the attached list choose the concepts attributed to various proponents of psychological theories:

Mahler Choose...

Erikson Choose...

Kohlberg Choose...

Choose...
Scaffolding
Social contract
Anal phase
Hypotheticodeduction
Operations
Animism
Autistic phase
Isolation

Explanation:

Margaret Mahler proposed a theory to describe how young children acquire a sense of identity separate from that of their mothers'. The first stage is 'normal autism' from birth to 2 months. In this stage, periods of sleep outweigh periods of arousal in a state reminiscent of intrauterine life. During symbiosis (age 2-5 months), mother-infant is perceived as a single fused entity.

Erik Erikson created an original and highly influential theory of psychological development and crisis occurring in periods that extended across the entire life cycle. Stage 6 takes place from about 21 years to about 40 years (young adulthood). Its focus is intimacy versus isolation.

Lawrence Kohlberg integrated Jean Piaget's concepts and described multiple stages of moral development within three significant levels of morality. The third and final stage is characterised by

the internalisation of moral principles. It is divided into two levels: at Level 5 the child defines moral behaviour in terms of the social contract and what is generally agreed to be for the public good, and at Level 6 it is based on genuine ethical principles that determine a person's personal moral code.

Ref: Boland R, Verduin M. Kaplan and Sadock's Synopsis of Psychiatry, 12th Edition. 2022. pp. 892-893, 902, 1071-1075.

Colman AM. Oxford Dictionary of Psychology, 4th Edition. 2015. p. 587.

The correct answer is: Mahler → Autistic phase, Erikson → Isolation, Kohlberg → Social contract

Question **25**

Not answered

Marked out of 5.00

Trust vs. mistrust
Autonomy vs. shame
Anal phase
Sensorimotor stage
Pre-operational stage
Concrete operational stage
Deductive reasoning
Oral phase
Initiative vs. guilt
Industry vs. inferiority

HiY Development CXEMI025

Psychosexual and cognitive development

For each of the following ages, choose options that correspond to the most appropriate stages of development from the above list

1. 0-1 year (Choose ONE)

2. 4-7 years (Choose TWO)

3. 7-12 years (Choose TWO)

Explanation: Erik Erikson proposed 8 developmental psychosocial stages. It includes basic trust vs. mistrust (birth to 12-18 months), autonomy vs. shame (18 months to 3 years), initiative vs. guilt (3-6 years), industry vs. inferiority (6-12 years), identity vs. role confusion (adolescence), intimacy vs. isolation (young adulthood), generativity vs. stagnation (middle adulthood), and ego integrity vs. despair (late adulthood). Jean Piaget proposed four important stages of cognitive development. It includes sensorimotor stage (0 to 2 years), pre-operational stage (2-7 years), concrete operational stage (7-11 years) and formal operational stage (more than 11 years). Hypothetico-deductive reasoning is a feature of formal operational stage, which develops in a proportion of children after the age of 12. Sigmund Freud proposed psychosexual stages that includes oral phase (birth to 18 months), anal phase (18 months - 3 years), phallic stage (3-5 years), latency stage (5 to 12 years) and genital stage (12 years onwards).

The correct answer is:

0-1 year (Choose ONE)- Oral phase,

4-7 years (Choose ONE)- Initiative vs. guilt, Pre-operational stage,

7-12 years (Choose TWO)- Concrete operational stage, Industry vs. inferiority
