Modelling

Learning theory in practice

For each of the following situations, identify the learning theory used in practice.

A cat bit a young child when she attempted to feed it. After that, the girl remains afraid of approaching the animal. — Choose...

A man with spider phobia is asked to relax and listen to music and presented initially with pleasant visual images. Later he is shown a picture of a spider. — Choose...

A rat is presented with a lever. Initially, he was given a food pellet when he moved towards the lever every time. Later the food pellets were delivered only upon touching the lever. Later, the delivery of food only occurred when the lever was pressed. — Choose...

A 6-year-old boy imitates the aggressive behaviour of his father, which alarms his mother — Choose...

Explanation:

Classical conditioning is one of two major forms of conditioning. It is the process of learning through which an initially neutral stimulus comes to elicit a particular response as a consequence of being paired repeatedly with an unconditioned stimulus. In classical conditioning, the responses are often autonomic. It is also called Pavlovian conditioning.

Reciprocal inhibition is a technique of behaviour therapy used to especially treat phobias by repeatedly evoking a response that is physiologically incompatible with anxiety, such as deep muscular relaxation, simultaneously with the anxiety-provoking phobic stimulus. The behavioral principle of **reciprocal inhibition** (Wolpe) states that anxiety and relaxation cannot coexist.

Shaping is a technique of operant conditioning that involves gradually building up a desired pattern of behaviour by selectively reinforcing closer and closer approximations to it, beginning with existing elements of the subject's behavioural repertoire, until the required responses are learned. It can be used to train animals more effectively than any other known method.

Modelling occurs when a person learns patterns of behaviour by imitating another person.

Ref: Colman AM. Oxford Dictionary of Psychology, 4th Edition. 2015. pp. 135, 471, 640, 693.

Semple D, Smyth R. Oxford handbook of psychiatry. Oxford university press; 2019 Jul 30. p. 908.

The correct answer is: A cat bit a young child when she attempted to feed it. After that, the girl remains afraid of approaching the animal. → Classical conditioning, A man with spider phobia is asked to relax and listen to music and presented initially with pleasant visual images. Later he is shown

a picture of a spider. → Reciprocal inhibition, A rat is presented with a lever. Initially, he was given a food pellet when he moved towards the lever every time. Later the food pellets were delivered only upon touching the lever. Later, the delivery of food only occurred when the lever was pressed. → Shaping, A 6-year-old boy imitates the aggressive behaviour of his father, which alarms his mother → Modelling

Types of Learning
Using the definitions given below, identify the types of learning principles applied

Learning results from consequences of one's actions and the resultant effect on the environment. The learning organism is active and instrumental on the environment. — Choose...

Learning takes place through repeated temporal association of two events. The learning organism is passive, respondent but not instrumental. — Choose...

Although new learning occurs slowly, in some situations solutions to a problem comes in an instant, with a sudden grasp of a concept. — Choose...

This type of learning combines both classic and operant models of learning and considers cognitive processes and social interactions to be relevant in human learning. — Choose...

Learning that occurs without any apparent reinforcement or reward. — Choose...

Choose...
Sensitization
Social learning
Habituation
Pseudo-conditioning
Latent learning
Operant conditioning
Discrimination learning
Cross sensitization
Classical conditioning
Insight learning

Explanation:

Operant conditioning is one of two major forms of conditioning. It is the learning process whereby the relative frequency of a response increases as a result of reward or reinforcement that is contingent on the response being emitted. It is also called respondent conditioning.

Classical conditioning is one of two major forms of conditioning. It is the process of learning through which an initially neutral stimulus comes to elicit a particular response as a consequence of being paired repeatedly with an unconditioned stimulus. In classical conditioning, the responses are often autonomic. It is also called Pavlovian conditioning.

Insight learning is the process by which the meaning or significance of a pattern or the solution of a problem suddenly becomes clear, often accompanied by a eureka moment or an aha experience.

Social learning refers to the processes by which social influences alter people's thoughts, feelings, and behaviour. The earliest social learning theories were simple operant conditioning theories based on reinforcement; more recent versions assign a major role to cognitive processes.

Latent learning occurs without any apparent reinforcement or reward, as when a rat explores a maze and is later shown to have learned to find its way around it. In human learning, the phenomenon is also called incidental learning or passive learning.

Ref: Colman AM. Oxford Dictionary of Psychology, 4 th Edition. 2015.

The correct answer is: Learning results from consequences of one's actions and the resultant effect on the environment. The learning organism is active and instrumental on the environment. → Operant conditioning, Learning takes place through repeated temporal association of two events. The learning organism is passive, respondent but not instrumental. → Classical conditioning, Although new learning occurs slowly, in some situations solutions to a problem comes in an instant, with a sudden grasp of a concept. → Insight learning, This type of learning combines both classic and operant models of learning and considers cognitive processes and social interactions to be relevant in human learning. → Social learning, Learning that occurs without any apparent reinforcement or reward. → Latent

learning

Flag question

Cancer chemotherapy and behavioural psychology

A middle-aged man is diagnosed with a skin tumour for which he is undergoing six months long radiotherapy and chemotherapy, administered at the same hospital every time by uniformed nurses and radiotherapists. This treatment has resulted in severe nausea and vomiting. Match one term from the given list of learning concepts to each of the following situations.

He develops nausea as soon as he enters the hospital, without even taking the drugs or seeing his therapy team.	Choose...
The nausea worsens as soon as he sees anyone in a white coat, including the lab workers and pharmacist.	Choose...
Whenever possible he avoids using the travel route via the hospital, to avoid nausea.	Choose...
He experiences nausea whenever he sees any tablet, even if it is not for his cancer, but he is not nauseous when taking them as capsules.	Choose...
His treatment is stopped, but he is followed up for next six months by the same team. Gradually his nausea subsides.	Choose...

Choose...
Extinction
Aversive conditioning
Avoidance learning
Negative reinforcement
Modelling
Sensitisation
Discrimination
Operant conditioning
Classical conditioning
Stimulus generalization
Chaining

Explanation:

Classical conditioning is one of two major forms of conditioning. It is the process of learning through which an initially neutral stimulus comes to elicit a particular response as a consequence of being paired repeatedly with an unconditioned stimulus. In classical conditioning, the responses are often autonomic. It is also called Pavlovian conditioning.

Stimulus generalization is the tendency for a learned response to a particular stimulus to be elicited by other stimuli that resemble it.

In avoidance situations, the organism learns to perform actions that prevent the delivery or presentation of an aversive event. The explanation of avoidance learning is subtle because it is difficult to identify an obvious reinforcer. Cues in the environment come to predict the aversive event, and consequently, they arouse anxiety or fear. The avoidance response can, therefore, be reinforced if it escapes from or reduces that fear.

Discrimination is the act or process of distinguishing between stimuli or of recognising or understanding the differences between things.

Extinction is a diminution in the strength or frequency of a conditioned response as a result of its having been elicited repeatedly without reinforcement.

Ref: Colman AM. Oxford Dictionary of Psychology, 4 th Edition. 2015. pp. 135, 211, 265, 751.

Boland R, Verduin M. Kaplan and Sadock's Synopsis of Psychiatry, 12th Edition. 2022. p. 1020.

The correct answer is: He develops nausea as soon as he enters the hospital, without even taking the drugs or seeing his therapy team. → Classical conditioning, The nausea worsens as soon as he sees anyone in a white coat, including the lab workers and pharmacist. → Stimulus generalization, Whenever possible he avoids using the travel route via the hospital, to avoid nausea. → Avoidance learning, He experiences nausea whenever he sees any tablet, even if it is not for his cancer, but he is not nauseous when taking them as capsules. → Discrimination, His treatment is stopped, but he is followed up for next six months by the same team. Gradually his nausea subsides. → Extinction

Question **4**

Not answered

Marked out of

Choose...
Stimulus generalization
Shaping
Reciprocal inhibition
Cognitive mapping
Chaining
Discriminative learning
Extinction
Stimulus preparedness
Classical conditioning
Premack principle

Psychological mechanisms

Identify one main mechanism involved for each of the following situations.

Tom is a seven-year-old boy who is told to finish his homework before he can go and play with his mates. Choose...

Miss. Y is a 23-year-old woman who has a history of spider phobia. She is put into a relaxed state by soothing music, suggestion and visualizing pleasant images. While she is in a relaxed state, she is shown a picture of a spider. Choose...

Lucy is a 7-year-old girl who is seeing a speech therapist for mutism. She only speaks in the presence of the therapist but not others. Choose...

Sam is a 3-year-old boy, who is learning to write. His mother appreciates him for holding his pencil correctly, then for scribbling something on the paper and later for writing something, which resembles a letter of the alphabet. Choose...

Explanation:

The Premack principle asserts that access to a preferred action will reinforce any action that is less preferred. Any behaviour that is preferred to a second behaviour will theoretically reinforce the second behaviour.

Reciprocal inhibition is a technique of behaviour therapy used to especially treat phobias by repeatedly evoking a response that is physiologically incompatible with anxiety, such as deep muscular relaxation, simultaneously with the anxiety-provoking phobic stimulus. The behavioral principle of **reciprocal inhibition** (Wolpe) states that anxiety and relaxation cannot coexist.

Discriminative learning is the ability to respond differently to different stimuli.

Shaping is a technique of operant conditioning that involves gradually building up a desired pattern of behaviour by selectively reinforcing closer and closer approximations to it, beginning with existing elements of the subject's behavioural repertoire, until the required responses are learned. It can be used to train animals more effectively than any other known method.

Ref: Boland R, Verduin M. Kaplan and Sadock's Synopsis of Psychiatry, 12th Edition. 2022. p. 1019.

Colman AM. Oxford Dictionary of Psychology, 4 th Edition. 2015. pp. 640, 693.

Semple D, Smyth R. Oxford handbook of psychiatry. Oxford university press; 2019 Jul 30. p. 908.

The correct answer is: Tom is a seven-year-old boy who is told to finish his homework before he can go and play with his mates. → Premack principle, Miss. Y is a 23-year-old woman who has a history of spider phobia. She is put into a relaxed state by soothing music, suggestion and visualizing pleasant images. While she is in a relaxed state, she is shown a picture of a spider. → Reciprocal inhibition, Lucy is a 7-year-old girl who is seeing a speech therapist for mutism. She only speaks in the presence of the therapist but not others. → Discriminative learning, Sam is a 3-year-old boy, who is learning to write. His mother appreciates him for holding his pencil correctly, then for scribbling something on the paper and later for writing something, which resembles a letter of the alphabet. → Shaping

Question **5**

Not answered

Marked out of 4.00

Operant conditioning

Identify the type of reinforcement using the descriptions given below.

This type of reinforcement is the least resistant to extinction Choose...

Choose...
Continuous reinforcement
Latent learning
Secondary reinforcers
Primary reinforcers
Intermittent Reinforcement
Variable interval reinforcement
Fixed interval reinforcement
Fixed ratio reinforcement
Variable ratio reinforcement

This type of reinforcement is the most resistant to extinction — Choose...

This type of reinforcement takes the longest to establish — Choose...

This type of reinforcement leads to highest rate of responding — Choose...

Explanation:

In operant conditioning reinforcement schedules can be continuous or partial (also called intermittent). In full/ continuous reinforcement schedules (also called contingency reinforcement), every behaviour is followed by a reinforcer. This makes learning quicker, but extinction occurs soon after few occasions when a reinforcer is not provided as the organism learns that there is no use in doing the same behaviour as it is not going to get anything. Vending machines where everytime you press a button after placing a pound coin in the slot are examples of continuous reinforcement. It takes only a short time to learn, but if once you fail to get the drink from a machine, you will become wary and stop using it soon. In partial or intermittent reinforcement schedules, only some instances of the behaviour get reinforced during the learning phase. This may be done in a ratio schedule where every nth behaviour can be reinforced or interval schedule where every nth second the behaviour gets reinforced. In ratio schedules, higher the ratio, higher the response rate.

Partial schedules can be of fixed ratio/interval or variable ratio/interval. In fixed-ratio (FR) schedule, a reward is given after a certain number of responses are made. For example, the locum on-calls are paid according to number of hours worked. The example of a rat receiving food pellet for every 3rd lever-press is also a fixed ratio (a constant 1:3 ratio). As more responses yield more reinforcement, only short pauses occur after each response. So, FR schedules produce the highest rate of responding. In fixed interval schedules, the time interval is fixed beforehand and is constant e.g. every 4th minute a pellet is given to the rat. Another example is your monthly salary. You get paid once a month (reward) no matter how many hours you work (response). As a result, most salaried workers tend to work slow and steady, only doing as much as they have to essentially do! In fixed interval schedules, a longer pause may be seen after reinforcement as the organism knows the reinforcement will not be happening for some reasonable time or attempts after this. Variable schedules generate a constant rate of response as the chance of obtaining a reward stays the same at any time and any instance of behaviour. Examples include buying lottery, gambling on horses, etc. This is difficult to extinguish, as rewards are unpredictable. Even when the organism goes without reward for long periods, the expectations will stay high and responses may even increase in vigour.

When we interpret an operation to be under control, we learn more quickly - as seen in fixed schedules, compared to intermittent schedules where learning is slower. But intermittent schedules are more resistant to extinction with the variable-ratio being the most resistant.

The correct answer is: This type of reinforcement is the least resistant to extinction → Continuous reinforcement, This type of reinforcement is the most resistant to extinction → Variable ratio reinforcement, This type of reinforcement takes the longest to establish → Intermittent Reinforcement, This type of reinforcement leads to highest rate of responding → Fixed ratio reinforcement

Question **6**

Choose...
Registration
Déjà vu
Recognition
Jamais vu
Recollection
Confabulation
Retrospective falsification
Recapitulation
Delusional elaboration

Terms related to memory

For each of the description below chose one most appropriate term from the given list

Reintegrating events using a variety of components — Choose...

Modifying memory in terms of attitudes and emotions — Choose...

Absence of the normal feeling of familiarity that accompanies

memory when visiting a place for the second time — Choose...

Feeling of familiarity that accompanies return of stored material to consciousness — Choose...

Explanation: Recollection is the reintegration of a complete event from a variety of different components and is a function of recall. For example, to remember the sequence of events on your wedding day requires recalling a number of separate items of information by exploring many different avenues.

Retrospective falsification involves applying 'emotional colour' to the recall of events.

Jamais vu refers to a pathology of familiarity that is the phenomenological antagonism of déjà vu. It is a form of paramnesia characterised by an erroneous belief of having never before seen or experienced something that one has in reality encountered before.

Recognition is the feeling of familiarity, which accompanies the return of stored material to consciousness. It is therefore not strictly part of the process of memory but is intimately connected.

The correct answer is: Reintegrating events using a variety of components → Recollection, Modifying memory in terms of attitudes and emotions → Retrospective falsification, Absence of the normal feeling of familiarity that accompanies memory when visiting a place for the second time → Jamais vu, Feeling of familiarity that accompanies return of stored material to consciousness → Recognition

Question **7**

Not answered

Marked out of 4.00

Flag question

Theories of Attention

For each of the statements given below, identify the names of the theory from the given list.

'People can only attend to one physical channel of information at a time' — Choose...

'Alternative information is simultaneously processed and can be attended to if required.' — Choose...

'The ability of people to switch their attention rapidly to a non-processed message.' — Choose...

'Irrelevant stimuli are attenuated' — Choose...

Choose...
Shiffrin and Schneider's divided attention theory
Equity theory
Cocktail party phenomenon
Social exchange theory
Attenuator model of selective attention
Schema theory
Broadbent's filter theory of attention
Dichotic listening theory
Group think
Cannon Bard theory

Explanation:

Broadbent's early selection filter theory suggests that our ability to process information is capacity limited. A temporary buffer system receives all information and passes it to a selective filter. The selection is based on physical characteristics of the information - one source is selected, and others are rejected. Processing two different information will take longer and will be less efficient as switching takes a substantial period.

Dichotic listening refers to feeding one message into the right ear and a different message simultaneously into left ear. Participants have to repeat one message aloud. This process is called Shadowing (first used by Cherry). This is a method to study selective attention. Divided attention can be tested using a dual-task technique whereby the individual is asked to attend and respond to both or all incoming messages.

Cocktail party effect is a concept related to selective attention. It is a term used to describe "the ability

of people to be able to switch their attention rapidly to a non-processed message" amidst the abundance of multiple other distracting stimuli. Certain types of stimuli e.g. the location of the speaker, the pitch of the voice or the use of familiar stimuli such as the listener's name, can provoke the swift switch between messages (also called the Lunch-Queue effect).

The correct answer is: 'People can only attend to one physical channel of information at a time' → Broadbent's filter theory of attention, 'Alternative information is simultaneously processed and can be attended to if required.' → Dichotic listening theory, 'The ability of people to switch their attention rapidly to a non-processed message.' → Cocktail party phenomenon, 'Irrelevant stimuli are attenuated' → Attenuator model of selective attention

Question **8**

Not answered

Marked out of 4.00

Theories of Emotion

For each of the following statements, choose the most appropriate names of theory from the attached list.

'Emotion is secondary to physiological changes and that there is a distinct pattern of changes for different emotions.' Choose...

The subjective experience of emotions is independent of physiological changes. Choose...

The cognitive appraisal conscious or unconscious always precedes emotional experience. Choose...

On perception of a stimulus, both physiological changes and a conscious experience of general arousal take place simultaneously which is then interpreted to either positive or negative valence and labelled appropriately. Choose...

Choose...
Cannon-Bard theory
Social exchange theory
Schema theory
James-Lange theory
Broadbent's filter theory
Cognitive appraisal theory
Schachter-Singer theory
Cognitive enhancement theory
Shiffrin and Schneider's theory
Contingency theory
Dichotic listening theory

Explanation:

James-Lange theory of emotions: Perception of a stimulus leads to bodily (skeletal and visceral) changes. The peripheral responses send feedback to the cortex via thalamus leading to the perception of the emotion.

Cannon-Bard theory: On the perception of a stimulus, thalamus coordinates signals to cortex leading to conscious experience and simultaneously sends signals to hypothalamus leading to physiological changes.

Schachter-singer labelling theory: On the perception of a stimulus, both physiological changes and a conscious experience of general arousal take place simultaneously. This generic arousal is then interpreted to either positive or negative and labelled appropriately according to the situational cues. This is also called jukebox theory or two-factor theory. If an appropriate label is not found, by default, negative appreciation of arousal occurs.

Lazarus cognitive appraisal theory states that appraisal precedes affective reaction - hence affective primacy cannot be true.

The correct answer is: 'Emotion is secondary to physiological changes and that there is a distinct pattern of changes for different emotions.' → James-Lange theory, The subjective experience of emotions is independent of physiological changes. → Cannon-Bard theory, The cognitive appraisal conscious or unconscious always precedes emotional experience. → Cognitive appraisal theory, On perception of a stimulus, both physiological changes and a conscious experience of general arousal take place simultaneously which is then interpreted to either positive or negative valence and labelled appropriately. → Schachter-Singer theory

Question **9**

Not answered

Marked out of

Choose...
Risky shift phenomenon
Groupthink
Obedience
Sociogram
Diffusion of responsibility
Conformity
Deindividuation
Pluralistic ignorance
Bystander intervention
Polarization

Group Processes

For each of the following definitions, identify the right term used to describe them from the list shown.

When individuals express their opinions separately and then group to decide upon the same matter the eventual outcome is likely to be more extreme than that of the group average. Choose...

People tend to make riskier decisions when working as members of a group than they would make when making the same decision as individuals. Choose...

It is the desire to achieve consensus and avoid dissent in group decisions. Choose...

It is a graphical representation of relationships in a group. Choose...

Explanation: There are various processes that influence individuals when making decisions as a part of a group. The group can make more risky decisions than what an individual him/herself is inclined to. This is called risky shift. A group discussion process can strengthen average individual inclinations and polarise the group in the direction where most individuals were heading already. This is called group polarisation. While making extreme decisions, the desire to agree with other members of a group can override rational judgment applicable in individual decision-making. This is called groupthink.

The correct answer is: When individuals express their opinions separately and then group to decide upon the same matter the eventual outcome is likely to be more extreme than that of the group average. → Polarization, People tend to make riskier decisions when working as members of a group than they would make when making the same decision as individuals. → Risky shift phenomenon, It is the desire to achieve consensus and avoid dissent in group decisions. → Groupthink, It is a graphical representation of relationships in a group. → Sociogram

Question **10**

Not answered

Marked out of 4.00

Choose...
Sociogram
Polarization
Bystander apathy
Groupthink
Risky shift phenomenon
Conformity
Obedience
Pluralistic ignorance
Diffusion of responsibility
Deindividuation

Altruism

For each of the following descriptions, identify the right term used to describe the psychological phenomena from the list provided.

The tendency of not to intervene in a situation due to the presence of others. Choose...

People feel that the responsibility is not theirs, and someone else will do something. Choose...

Members of a group convince each other that there is no problem. Choose...

The individual behaviour of group members is less important than that of the whole group. Choose...

Explanation:

Bystander apathy: When alone, individuals will typically intervene if another person is in need of help: this is called bystander intervention. But intervention becomes less likely to an extent that no single person will intervene from a crowd or group of observers when someone is in need of help. This is called bystander apathy or Genovese effect.

Pluralistic ignorance: This refers to members of a crowd looking at each other for signs of distress, but

himself/herself remaining calm, leading to misappraisal of the situation being safe leading to lack of intervention.

Diffusion of responsibility: Similar to social loafing - 'I have some responsibility, but so do others; let someone else help'

Dissolution of responsibility: If not knowing what others are doing, rationalizes that someone would have helped the victim.

Deindividuation (Leon Festinger 1952) represents the situation where anti-normative behaviour appears in group settings in which "individuals are not seen or paid attention to as individuals". It is immersion in a group to the point at which the individual ceases to be seen as such.

The correct answer is: The tendency of not to intervene in a situation due to the presence of others. → Bystander apathy, People feel that the responsibility is not theirs, and someone else will do something. → Diffusion of responsibility, Members of a group convince each other that there is no problem. → Pluralistic ignorance, The individual behaviour of group members is less important than that of the whole group. → Deindividuation

Question **11**

Not answered

Marked out of 3.00

Social Psychology

For each of the following descriptions, identify the right term used to describe the psychological phenomena from the list provided;

Classic studies by Milgram in which the majority of participants delivered the maximum shock voltage, showing that people would carry out orders under certain conditions even if these exceeded the bounds of their usual beliefs. — Choose...

The normative social influence that forces an individual to agree with the group view despite holding a different personal view. — Choose...

The larger a group is, the lesser the individual performance as one thinks the others will do the job and bring the results. — Choose...

Choose...
Obedience
Diffusion of responsibility
Polarization
Deindividuation
Pluralistic ignorance
Groupthink
Bystander apathy
Social loafing
Risky shift phenomenon
Conformity

Explanation:

The Milgram experiment is a famous experimental procedure introduced in 1963 by the US psychologist Stanley Milgram to study obedience to authority. Milgram conducted a series of experiments in which approximately two-thirds of participants ('teachers') administered what they believed to be extremely painful and possibly lethal electric shocks to an innocent victim ('learner') when instructed to do so by an authoritative experimenter ('experimenter').

Conformity is a form of social influence in which a person yields to group pressure in order to fit in.

Social loafing is the tendency to exert less effort on a task when working as part of a cooperative group than when working on one's own – one reason why 'many hands make light work'. The phenomenon has been replicated across a variety of tasks, and evidence has shown that it is greatly reduced by making individual contributions identifiable within the group.

Ref: Colman AM. Oxford Dictionary of Psychology, 4 th Edition. 2015.

The correct answer is: Classic studies by Milgram in which the majority of participants delivered the maximum shock voltage, showing that people would carry out orders under certain conditions even if these exceeded the bounds of their usual beliefs. → Obedience, The normative social influence that forces an individual to agree with the group view despite holding a different personal view. → Conformity, The larger a group is, the lesser the individual performance as one thinks the others will do the job and bring the results. → Social loafing

Question **12**

Not answered

Marked out of 4.00

Social Power

With the descriptions given below, identify the type of social power from the list of options provided.

The leader has a position of formal authority	Choose...
The follower identifies with the leader and consequently grants him or her influence	Choose...
The leader can administer or threaten punishments for 'unacceptable behaviours.'	Choose...
Followers will allow themselves to be influenced because they perceive the leader to have expertise	Choose...
This is based on the perception that someone has the right to prescribe behaviour due to election	Choose...

Choose...
Reward power
Legitimate power
Expert power
Coercive power
Informational power
Democratic power
Autocratic power
Referent power

Explanation:

Reward Power is based on the "perceived ability to give positive consequences or remove negative ones".

Coercive Power is the "perceived ability to punish those who not conform to your ideas or demands".

Legitimate Power is "based on the perception that someone has the right to prescribe behaviour due to election or appointment to a position of responsibility".

Referent Power is through association with others who possess the power (e.g., a colleague who is closer to the management authorities).

Expert Power is "based on having distinctive knowledge, expertness, ability or skills)". Information Power is "based on controlling the information needed by others in order to reach an important goal". Excerpt from Power, Essence and the Organisation. (n.d.). Retrieved from http://www.iasag.ch/docs/article.lammers.power.essence.pdf

The correct answer is: The leader has a position of formal authority → Legitimate power, The follower identifies with the leader and consequently grants him or her influence → Referent power, The leader can administer or threaten punishments for 'unacceptable behaviours.' → Coercive power, Followers will allow themselves to be influenced because they perceive the leader to have expertise → Expert power, This is based on the perception that someone has the right to prescribe behaviour due to election → Democratic power

Marked out of 4.00

Memory types

Identify the type of memory which is being referred to, for each of the following situations.

A 45-year-old man was involved in a road traffic accident and was unconscious for a week. On examination, he has no memory for any events for a period of a week prior to the accident.	Choose...
A 76-year-old man was found wandering and was brought to the A&E by the police. On mini-mental state examination, when you ask him to remember the three objects, he is unable to immediately repeat them.	Choose...
An 83-year-old woman has been diagnosed with Alzheimer's disease. She enjoys playing piano, which she used to do for a long	Choose...

Choose...
Anterograde memory
Infantile memory
Retrograde memory
Episodic memory
False memory
Working memory
Autobiographical memory
Semantic memory
Procedural memory

time even before her illness began. Which type of memory remains intact? Choose...

When answering the question, 'What is the capital of France?' what is the type of memory that Mr. P was using? Choose...

Explanation:

Retrograde amnesia is loss of memory for events or experience before a traumatic event or incident that causes the amnesia.

Working memory is a temporary store for recently activated items of information that are currently occupying consciousness and that can be manipulated and moved in and out of short-term memory.

The performance of tasks such as typing, swimming, or playing an instrument are expressions of prior learning that differ from episodic memory in that there is no active awareness that memory is being searched in undertaking the particular skill. This type of memory is known as implicit, procedural, or skills memory.

Memory for factual knowledge and autobiographical events is collectively termed declarative memory. Declarative (also known as explicit) memory is of two types: episodic memory or memory for specific events (such as going to the shop this morning) and semantic memory or memory for abstract facts such as the capitals of countries.

Ref: Colman AM. Oxford Dictionary of Psychology, 4th Edition. 2015. p. 657, 824.

Casey P, Kelly B. Fish's clinical pathology: Signs and symptoms in psychiatry, 4th Edition. 2019. p. 64.

Boland R, Verduin M. Kaplan and Sadock's Synopsis of Psychiatry, 12th Edition. 2022. p. 1025.

The correct answer is: A 45-year-old man was involved in a road traffic accident and was unconscious for a week. On examination, he has no memory for any events for a period of a week prior to the accident. → Retrograde memory, A 76-year-old man was found wandering and was brought to the A&E by the police. On mini-mental state examination, when you ask him to remember the three objects, he is unable to immediately repeat them. → Working memory, An 83-year-old woman has been diagnosed with Alzheimer's disease. She enjoys playing piano, which she used to do for a long time even before her illness began. Which type of memory remains intact? → Procedural memory, When answering the question, 'What is the capital of France?' what is the type of memory that Mr. P was using? → Semantic memory

Question **14**

Not answered

Marked out of 3.00

Flag question

HiY Psychology CXEMI014

Ethical bodies

Which of the above organisations/consensus are responsible for each of the following practice?

1. Good medical practice

2. Ethical human research (Choose TWO)

Nuremberg Code
General Medical Council
Helsinki Declaration
Royal College of Psychiatrists
Department of health
National Institute of Clinical excellence
National Institute of Mental Health

Explanation:

Good medical practice is a publication by the General Medical Council (GMC) that describes what it

means to be a good doctor. The guidance is split into four sections that describe the professional values and behaviour expected of any doctor registered with the GMC.

The first ethical code for research was the Nuremberg Code, arising in the aftermath of Nazi research atrocities brought to light in the post-World War II Nuremberg Trials in Germany. This set of international research standards sought to prevent gross research misconduct and abuse of vulnerable and unwitting research subjects by establishing specific human subject protective factors. The Nuremberg Code set the standard for every subsequent attempt to regulate human experimentation. Its first principle remains its most important: the requirement of the voluntary, competent, informed, and understanding consent of the human subject.

The Declaration of Helsinki, adopted by the World Medical Association's General Assembly in 1964, is the most important set of guidelines about research on human participants. It both reflects and shapes the ethos of international research ethics. It is a living instrument and is reviewed and revised regularly. Its latest revision was in 2013.

Ref: https://www.gmc-uk.org/ethical-guidance/ethical-guidance-for-doctors/good-medical-practice

Annas GJ. Beyond Nazi war crimes experiments: the voluntary consent requirement of the Nuremberg Code at 70. American journal of public health. 2018 Jan;108(1):42-6.

Malik AY, Foster C. The revised Declaration of Helsinki: cosmetic or real change?. Journal of the Royal Society of Medicine. 2016 May;109(5):184-9.

The correct answer is:

Good medical practice - General Medical Council

Ethical human research (Choose TWO) - Nuremberg Code, Helsinki Declaration

Question **15**

Not answered

Marked out of

Sociology of Psychiatry

Select one option for each of the following.

A patient who had been living in an institution for many years now cannot cook for himself and live in a flat independently. — Choose...

A member of the staff believes all mentally ill people are not able to decide about what they want. — Choose...

A passenger on a coach laughs to himself and argues with himself in a loud manner. — Choose...

Choose...
Normalisation
Overgeneralization
Rationalisation
Residual rule breaking
Aversion
Institutionalization
Self-actualisation

Explanation:

Long-term hospitalization is often associated with "deskilling, where patients might lose social and vocational skills and the ability to set goals. This is also known as institutionalization.

Question 2 highlights overgeneralization ('lumping tendency') a common cognitive distortion in inexperienced professionals.

Thomas Scheff proposed a labelling theory of mental illness and suggested that persons labelled mentally disturbed ('deviant') are in fact breaking "residual" rules - a set of unwritten norms of social life. According to him 'residual rules' included diverse kinds of violations for which the culture provides no explicit label. For the convenience of the society, these violations get lumped together into a residual category e.g. witchcraft and spirit possession in the past and mental illness in the contemporary society (Scheff 1999; 55)

The correct answer is: A patient who had been living in an institution for many years now cannot cook for himself and live in a flat independently. → Institutionalization, A member of the staff believes all mentally ill people are not able to decide about what they want. → Overgeneralization, A passenger on

a coach laughs to himself and argues with himself in a loud manner. → Residual rule breaking

Learning Theory - vignettes

For each of the following clinical situations, choose the one option, which describes it more appropriately.

A rat is presented with a lever. When he pressed the lever accidentally, the food was delivered. Impressed by the food rewards, the rat now presses the lever frequently. Choose...

A cat was placed in a big cage. When it started to explore the cage, it received electric shocks when it walked around certain parts of the cage. After few minutes, the cat started moving around only in those areas that were shock-free. Choose...

The mother of a 4-year-old child helped her in solving a jigsaw puzzle. She showed the girl how to start from the whole puzzle and then removed pieces one by one. Choose...

Choose...
Avoidance learning
Reciprocal inhibition
Premack principle
Latent learning
Operant conditioning
Cognitive mapping
Shaping
Backward chaining
Stimulus preparedness
Forward chaining

Explanation:

Operant conditioning is one of two major forms of conditioning. It is the learning process whereby the relative frequency of a response increases as a result of reward or reinforcement that is contingent on the response being emitted. It is also called respondent conditioning.

Conditioned avoidance learning is a form of operant conditioning in which the organism must make a particular response to evade punishment.

Chaining is a behaviour-analytic strategy used to teach complex skills by breaking down these skills into individual responses and teaching them sequentially. One chaining strategy is backward chaining, in which the instructor starts teaching the individual from the last step to the first step of the behaviour chain.

Ref: Colman AM. Oxford Dictionary of Psychology, 4 th Edition. 2015.

Muharib R et al. Backward chaining and speech-output technologies to enhance functional communication skills of children with autism spectrum disorder and developmental disabilities. Augmentative and Alternative Communication. 2019 Oct 2;35(4):251-62.

The correct answer is: A rat is presented with a lever. When he pressed the lever accidentally, the food was delivered. Impressed by the food rewards, the rat now presses the lever frequently. → Operant conditioning, A cat was placed in a big cage. When it started to explore the cage, it received electric shocks when it walked around certain parts of the cage. After few minutes, the cat started moving around only in those areas that were shock-free. → Avoidance learning, The mother of a 4-year-old child helped her in solving a jigsaw puzzle. She showed the girl how to start from the whole puzzle and then removed pieces one by one. → Backward chaining

Cultural Psychology

With the descriptions given below, identify which of the following best describes this process during resettlement in UK from overseas?

A 45-year-old Sri Lankan refugee wants to retain his cultural identity while maintaining contact with members of the new culture. Choose...

A 36-year-old Indian woman does not want to seek contact with the new

Choose...
Accommodation
Union
Assimilation
Separation
Socialization
Marginalisation
Acclimatization
Integration
Disintegration

culture and would like to maintain the original cultural identity. Choose...

A 46-year-old Polish gentleman living in England takes on the values and attitudes of the English culture and retains only minimal values from his original culture. Choose...

A 33-year-old South African woman is not only shedding her original identity and cultural values but also not seeking contact with new cultural group. Choose...

Explanation:

Berry proposed a bidimensional acculturation model under the assumption that adapting to the host culture does not necessarily lead to the rejection of the origin culture but that migrants' attitudes toward the host and origin cultures are mutually independent. Based on this logic, he proposed four types of acculturation strategies:

1) Assimilation – rejecting the origin culture and embracing the host culture
2) Separation – maintaining the origin culture and abandoning the host culture
3) Marginalisation – rejecting both cultures
4) Integration – embracing both cultures

Ref: Ma Z, Xia Y. Acculturation strategies, age at migration, and self-rated health: An empirical study on internal migrants in China. Social Science Research. 2021 Jan 1;93:102487.

The correct answer is: A 45-year-old Sri Lankan refugee wants to retain his cultural identity while maintaining contact with members of the new culture. → Integration, A 36-year-old Indian woman does not want to seek contact with the new culture and would like to maintain the original cultural identity. → Separation, A 46-year-old Polish gentleman living in England takes on the values and attitudes of the English culture and retains only minimal values from his original culture. → Assimilation, A 33-year-old South African woman is not only shedding her original identity and cultural values but also not seeking contact with new cultural group. → Marginalisation

Question **18**

Not answered

Marked out of 3.00

Behaviourism

Identify the learning theory principles used in each of the following situations.

A boy with learning disabilities is toilet trained by successively rewarding behaviours that approximate final desired outcome. Choose...

A boy who is fond of Spiderman dresses like Spiderman and attempts adventurous sports to be like his favourite hero. Choose...

A man with a desire to touch women in a crowded tube keeps this impulse under control by imagining that he will be arrested and imprisoned for sexual offence. Choose...

Choose...
Covert reinforcement
Chaining
Aversive conditioning
Reciprocal inhibition
Covert sensitisation
Classical conditioning
Social learning
Flooding
Shaping
Operant conditioning
Punishment
Blocking

Explanation:

Shaping is a form of operant conditioning where a desirable behaviour pattern is learnt by the successive reinforcement of responses closer to the desired one.

Modelling is a mode of social learning behaviour often seen in school going children.

Reduction in the frequency of a behaviour (often undesirable behaviour) by associating it with

imagined unpleasant consequences is called covert sensitisation.

The correct answer is: A boy with learning disabilities is toilet trained by successively rewarding behaviours that approximate final desired outcome. → Shaping, A boy who is fond of Spiderman dresses like Spiderman and attempts adventurous sports to be like his favourite hero. → Social learning, A man with a desire to touch women in a crowded tube keeps this impulse under control by imagining that he will be arrested and imprisoned for sexual offence. → Covert sensitisation

Question **19**

Marked out of 3.00

Learning theories - illustrations

Identify the learning theory principles used in each of the following situations.

To train a 4-year-girl not to bite her nails, her mother applies bitter oil to her lips whenever she bites her nails. Choose...

Disulfiram is prescribed to a 36- year-old alcohol dependent patient. Twice when lapsed into drinking, he developed severe physical discomfort. He now remains abstinent for last two years. Choose...

To train a 4-year-old boy to say "goodbye," his mother gives him a candy whenever he waves goodbye to someone. Choose...

Choose...
desensitization
reciprocal inhibition
extinction
negative reinforcement
variable ratio reinforcement
hypnosis
avoidance
aversive conditioning
punishment
modelling
flooding
continuous reinforcement
positive reinforcement
variable interval reinforcement

Explanation:

Punishment is any stimulus that an organism seeks to avoid or escape. Negative reinforcement is not punishment but almost the reverse, namely the withdrawal of punishment.

Aversive conditioning is a technique of behaviour therapy used to eliminate undesirable habits, like cigarette smoking, by repeatedly pairing unpleasant or painful stimuli such as electric shock, or responses such as nausea (induced by a drug such as disulfiram), with the unwanted behaviour or associated stimuli.

In operant conditioning, reinforcement refers to any stimulus that, if it is presented soon after a response, **increases** the relative frequency with which that response is emitted in the future. Reinforcement can be **positive** (behaviour is followed by a desirable outcome) or **negative** (behaviour is followed by removal of an aversive stimulus).

Ref: Colman AM. Oxford Dictionary of Psychology, 4 th Edition. 2015.

The correct answer is: To train a 4-year-girl not to bite her nails, her mother applies bitter oil to her lips whenever she bites her nails. → punishment, Disulfiram is prescribed to a 36- year-old alcohol dependent patient. Twice when lapsed into drinking, he developed severe physical discomfort. He now remains abstinent for last two years. → aversive conditioning, To train a 4-year-old boy to say "goodbye," his mother gives him a candy whenever he waves goodbye to someone. → positive reinforcement

Learning principles

Identify the learning theory principles used in each of the following situations.

An IT firm introduces an escalating bonus system whereby workers who achieve certain targets are rewarded with rising bonuses irrespective of the time taken by them to attain the target. Choose...

An angler on average gets five meaty fishes everyday when

Choose...
Full reinforcement
Backward conditioning
Trace conditioning
Fixed ratio reinforcement
Fixed interval reinforcement
Shaping
Variable interval reinforcement
Continuous reinforcement
Reciprocal inhibition
Variable ratio reinforcement

w

he goes out fishing. Sometimes all of these fishes are caught within an hour; on other days he may have to wait for nearly 9 hours for a single catch. Choose...

NHS employees are paid every month irrespective of targets achieved or competitive performance. Choose...

Explanation: In fixed ratio schedule every nth (e.g., fifth, tenth) response is rewarded. Hence, target-oriented bonuses are in line with fixed-ratio schedules.In variable ratio reinforcement, every nth response is rewarded on average, but the gap between two rewarded responses is highly variable. This schedule is also seen in gambling, apart from fishing.This refers to consistently regular reinforcement at specific time intervals. The desired behaviour may become sluggish immediately after reinforcement, catching up during the later part of the interval.

The correct answer is: An IT firm introduces an escalating bonus system whereby workers who achieve certain targets are rewarded with rising bonuses irrespective of the time taken by them to attain the target. → Fixed ratio reinforcement, An angler on average gets five meaty fishes everyday when he goes out fishing. Sometimes all of these fishes are caught within an hour; on other days he may have to wait for nearly 9 hours for a single catch. → Variable ratio reinforcement, NHS employees are paid every month irrespective of targets achieved or competitive performance. → Fixed interval reinforcement

Question **21**

Not answered

Marked out of 4.00

Applied learning theory

For each of the following clinical situations, choose one most appropriate description.

A 6-year-old girl usually plays with her dog without fear. One day the dog accidentally bites the child. She then becomes fearful of approaching the dog. Choose...

A 7-year-old child is told to complete his homework before he can play with his friends. Choose...

A 15-year-old boy with spider phobias is put into a relaxed state by suggestion and soothing music. While he is in this relaxed state, he is shown the photograph of a spider. Choose...

A 4-year-old child is learning to write. She is appreciated by her parents for holding the pen properly, then for scribbling something on the notepad, later writing something that closely resembles a letter and finally writes the letter clearly. Choose...

Choose...
Cognitive mapping
Operant conditioning
Shaping
Stimulus preparedness
Reciprocal inhibition
Premack principle
Latent learning
Chaining
Classical conditioning
Stimulus generalization

Explanation:

In case 1, the young girl has learnt an association between the pain response and the dog after a single instance of stimulus-response pairing.

Case 2 exemplifies the Premack principle, which states that a high-frequency behaviour can be used to reinforce a low-frequency behaviour. This is also called as Grandma's rule - eat the spinach to get the dessert. This is nothing but positive reinforcement but instead of a material reinforcer, an already existing behaviour (eating dessert) is linked to desired response (eating spinach).

Case 3 exemplifies reciprocal inhibition (Wolpe). If a stimulus with a desired response and a stimulus with an undesired response are presented together repeatedly, then incompatibility leads to a reduction in the undesired response. This is evident when your dog barks at your friend; try hugging him in front of your dog every time the dog barks (!), slowly the dog will stop barking at your friend. This is used

in relaxation therapy for anxiety and systematic desensitisation.

Case 4 describes shaping, a form of operant conditioning in which a desirable behaviour pattern is learnt by the successive reinforcement of behaviours closer to the desired one (successive approximation). This is used in training animals in circus where the dog is reinforced when it runs towards the circle, then when it jumps near the circle, then when it jumps through the circle and at last when it jumps through the circle of fire.

The correct answer is: A 6-year-old girl usually plays with her dog without fear. One day the dog accidentally bites the child. She then becomes fearful of approaching the dog. → Classical conditioning, A 7-year-old child is told to complete his homework before he can play with his friends. → Premack principle, A 15-year-old boy with spider phobias is put into a relaxed state by suggestion and soothing music. While he is in this relaxed state, he is shown the photograph of a spider. → Reciprocal inhibition, A 4-year-old child is learning to write. She is appreciated by her parents for holding the pen properly, then for scribbling something on the notepad, later writing something that closely resembles a letter and finally writes the letter clearly. → Shaping

Question **22**

Theories in Psychology

For each of the following statements, choose the most appropriate theories from the list provided.

This theory states that people are selfish while deciding on relationships; preference is for relationships that offer the 'greatest gains' with 'least expense'. Choose...

This theory introduces the concept of 'fairness' with approximately equal gains in relationships between both individuals. Choose...

The letter "O" will automatically grab attention in a page full of X's. This suggests that attention involves automatic processes. Choose...

Choose...
Group think
Social exchange theory
Shiffrin and Schneider's theory
Cocktail party phenomenon
James-Lange theory
Schema theory
Equity theory
Broadbent's filter theory of attention
Cognitive appraisal theory
Contingency theory
Cannon-Bard theory

Explanation:

Social exchange theory claims that much, if not most, of our social behaviour is influenced by the expectation that our action towards others will be reciprocated in some way. Relationships are based on a mutual exchange of benefits.

Equity theory suggests that people try to maintain a balance between what they put into a relationship and what they get out of it. Most people would expect to receive rewards from a relationship, which are roughly proportional to the contributions they put into it.

Shiffrin and Schneider's theory of attention summarized evidence pointing towards two types of processing - controlled and automatic processing. Automatic processing involves attention to patterns and deviations. Controlled processing is employed when evaluating a situation in more detail.

The correct answer is: This theory states that people are selfish while deciding on relationships; preference is for relationships that offer the 'greatest gains' with 'least expense'. → Social exchange theory, This theory introduces the concept of 'fairness' with approximately equal gains in relationships between both individuals. → Equity theory, The letter "O" will automatically grab attention in a page full of X's. This suggests that attention involves automatic processes. → Shiffrin and Schneider's theory

Question **23**

Personality tests

Not answered

Marked out of 4.00

Flag question

For each of the following tests given below, choose their correct names from the list provided.

This test is a way of measuring personality along the dimensions of extroversion-introversion and neuroticism-stability — Choose...

It is one of the objective personality tests that includes hypochondriasis as a personality factor — Choose...

A projective personality test with pictures of ambiguous persons and scenes to make up a story — Choose...

This test is useful to assess premorbid intelligence — Choose...

Choose...
Wisconsin card sorting test
Raven's progressive matrices
Minnesota multiphasic personality inventory
Thematic apperception test
Trail making test
Stroop test
Eysenck Personality Inventory
Paired associates test
Rey-Osterreith test
Rorschach ink blot test
National adult reading test

Explanation:

The Eysenck Personality Inventory is a questionnaire designed to measure two major dimensions of personality, namely extraversion and neuroticism, according to the theory of personality propounded by the German-born British psychologist Hans Eysenck.

The Minnesota Multiphasic Personality Inventory (MMPI) is a self-report questionnaire consisting of 567 questions covering eight areas of psychopathology and two areas of personality type. The scales are: Hypochondriasis, Depression, Hysteria, Psychopathic deviate, Masculinity-femininity, Paranoia, Psychasthenia, Schizophrenia, Hypomania, and Social introversion. There are also four additional validity (test-taking attitude) scales.

The thematic apperception test is a projective personality test. It consists of a series of 10 black-and-white pictures that depict individuals of both sexes and of different age groups, who are involved in a variety of different activities. The stories that the patient makes up concerning the pictures, according to the projective hypothesis, reflect the patient's own needs, thoughts, feelings, stresses, wishes, desires, and views of the future.

First published in 1982, the 50-item National Adult Reading Test (NART) is a widely adopted method for estimating premorbid intelligence both for clinical and research purposes.

Ref: Colman AM. Oxford Dictionary of Psychology, 4 th Edition. 2015. p. 269, 469.

Semple D, Smyth R. Oxford handbook of psychiatry. Oxford university press; 2019 Jul 30. p. 96.

Bright P et al. The National Adult Reading Test: restandardisation against the Wechsler adult intelligence scale—fourth edition. Neuropsychological Rehabilitation. 2018 Aug 18;28(6):1019-27.

The correct answer is: This test is a way of measuring personality along the dimensions of extroversion-introversion and neuroticism-stability → Eysenck Personality Inventory, It is one of the objective personality tests that includes hypochondriasis as a personality factor → Minnesota multiphasic personality inventory, A projective personality test with pictures of ambiguous persons and scenes to make up a story → Thematic apperception test, This test is useful to assess premorbid intelligence → National adult reading test

Question **24**

Not answered

Marked out of 4.00

Memory

Identify the type of memory which is being tested.

Mr. X is shown a list of words and asked to remember as many words as possible. — Choose...

Choose...
Procedural memory
Recognition memory
Semantic memory
Cued memory
Repressed memory
Flashbulb memory
Free recall memory
Infantile memory
False memory

Choose...

Mr. Y is shown a list of words and asked to remember a supermarket grocery item in the list that starts with the letter 'B'.

Choose...

Mr. Z is shown a list of words. He is then shown an another list of words and asked which of those appeared on the first list.

Choose...

Mrs. Q has early dementia. She is still able to drive her car.

Choose...

Explanation:

Recognition is the act or process of perceiving or identifying information as matching or being the same as information that has been remembered. It is often contrasted with 'recall' which involves reproduction of remembered information without cues. Recognition is generally easier than recall. In free recall memory paradigm, subjects are required to study a list of items that are later recalled in any order. A different way of testing memory involves merely showing subjects the previously learnt words in a list format and asking them whether they recognize the items. These target words are mixed in with distractors (or foils) that they have not seen.

Cued recall is the retrieval of information from memory with the help of cues, typical examples of such cues being the first letter of a word or name to be remembered, or the category to which the item of information belongs to (such as 'a kind of food').

The performance of tasks such as typing, swimming, or playing an instrument are expressions of prior learning that differ from episodic memory in that there is no active awareness that memory is being searched in undertaking the particular skill. This type of memory is known as implicit, procedural, or skills memory.

Ref: Yonelinas AP et al. Recollection and familiarity: Examining controversial assumptions and new directions. Hippocampus. 2010 Nov;20(11):1178-94.

Colman AM. Oxford Dictionary of Psychology, 4th Edition. 2015. p. 181.

Casey P, Kelly B. Fish's clinical pathology: Signs and symptoms in psychiatry, 4th Edition. 2019. p. 64.

The correct answer is: Mr. X is shown a list of words and asked to remember as many words as possible. → Free recall memory, Mr. Y is shown a list of words and asked to remember a supermarket grocery item in the list that starts with the letter 'B'. → Cued memory, Mr. Z is shown a list of words. He is then shown an another list of words and asked which of those appeared on the first list. → Recognition memory, Mrs. Q has early dementia. She is still able to drive her car. → Procedural memory

Question **25**

Not answered

Medical Ethics - Principles

Identify one principle for each of the following.

Choose...
Paternalism
Justice
Autonomy
Beneficence
Utilitarianism
Conscience
Non-maleficence
Empiricism
Balanced decision

Choose...

During the second world war, the Nazi medico-military programme prisoners were shot in order to study gunshot wounds.

Choose...

You decide that a patient who has previously developed renal impairment on lithium carbonate should not be treated with it for a second time due to the risk of developing the condition again.

Choose...

A general manager of a regional psychiatric service has had her budget significantly reduced. She has to choose to cut either a day hospital service or an early intervention service.

A woman has a probable bone cancer discovered on a routine bone scan to detect osteoporosis. She is not informed about the suspected malignant tumour but is followed up with serial bone scans every few months to see if it is growing. Choose...

A 76-year-old man was diagnosed with Parkinson disease dementia. He is due to be treated with antidementia drugs. He has been offered a choice to choose oral tablets or transdermal patch. Choose...

Explanation:

The unacceptable Nazi medical experiments can be considered as an instance of extreme utilitarianism. In Nazi medico-military programme, prisoners were shot to study gunshot wounds, the consequentialist argument being the greater good for number of people in the future as a result of these experiments.

Non-maleficence is often the reason for avoid rechallenging with drugs causing adverse effects.

Justice is the primary ethical consideration in resource allocation; it is concerned with fairness or equity in distributing goods to people. Justice means ensuring that as far as possible all sections of the community get their 'fair share'of those resources.

As highlighted by Sullivan et al., "In certain terminal illnesses, questions often arise concerning how much truth to tell. When, if ever, is a physician justified in withholding information? Can too much information be harmful? These conflicts between benevolent paternalism on the part of the physician and an increasing interest on the part of the patient to preserve autonomy are not easily resolved".

Offering choices among medications is a way of respecting patient's autonomy.

Ref: Sullivan et al., Truth-telling and patient diagnoses. Retrieved from http://jme.bmj.com/content/27/3/192.full

The correct answer is: During the second world war, the Nazi medico-military programme prisoners were shot in order to study gunshot wounds. → Utilitarianism, You decide that a patient who has previously developed renal impairment on lithium carbonate should not be treated with it for a second time due to the risk of developing the condition again. → Non-maleficence, A general manager of a regional psychiatric service has had her budget significantly reduced. She has to choose to cut either a day hospital service or an early intervention service. → Justice, A woman has a probable bone cancer discovered on a routine bone scan to detect osteoporosis. She is not informed about the suspected malignant tumour but is followed up with serial bone scans every few months to see if it is growing. → Paternalism, A 76-year-old man was diagnosed with Parkinson disease dementia. He is due to be treated with antidementia drugs. He has been offered a choice to choose oral tablets or transdermal patch. → Autonomy

Question **26**

Not answered

Choose...
Divided attention
Stroop effect
Selective attention
Automatic processing
Controlled processing
Sustained attention
Focused attention
Alternating attention

Attention

Choose the type of attentional model involved in each of the following.

This requires conscious attention and is heavily demanding Choose...

Ability to focus on two different tasks at the same time Choose...

Difficulty in overriding automatic processing with conscious visual control Choose...

Ability to maintain a constant behavioural response during continuous and repetitive activity Choose...

Explanation:

Controlled processing requires conscious attention, places heavy demands, and is capacity limited.

Divided attention is the highest level of attention that is much more difficult to achieve within the same (e.g. visual) compared to multiple modalities (visual and auditory). This effect is seen during Stroop colour word test. The test is based on the observation that individuals can read words faster through automatic processing, than when they are asked to identify and name colours of the presented words. It requires two strategies; selective attention to the primary stimulus (colour) and inhibition of the predominant tendency to name the word or the distracter stimulus. It is thought to measure interference control and requires the inhibition of an over-learned automatic response. (Ref: Thambirajah MS. Psychological Basis of Psychiatry (2005); pg 145).

Sustained attention is the ability to maintain a consistent behavioral response during continuous and repetitive activity. It is also called vigilance or concentration.

The correct answer is: This requires conscious attention and is heavily demanding → Controlled processing, Ability to focus on two different tasks at the same time → Divided attention, Difficulty in overriding automatic processing with conscious visual control → Stroop effect, Ability to maintain a constant behavioural response during continuous and repetitive activity → Sustained attention

Question **27**

Marked out of 5.00

Social Psychiatry

Identify the correct terms used in social psychiatry to describe following situations.

A man standing alone in a lonely road helped another person in trouble. Choose...

A man stole a bottle of water from a shop. He was sentenced for one month "so that all other offenders know the consequences of shop-lifting." Choose...

An affable person becomes violent when he participates in a rally along with a number of charged-up individuals. Choose...

During a committee meeting, some of the employees did not make much of an effort and had few suggestions. These employees had made a much greater effort on other tasks in which they worked alone. Choose...

A politician is giving a talk to persuade the public regarding his views about economic repression and the need for more borrowing to improve it. Choose...

Choose...
Social facilitation
Conformity
Risky shift phenomenon
Associative learning
Social loafing
Bystander intervention
Overt aggression
Obedience
Minority influence

Explanation:

When alone, individuals often intervene if another person is in need of help: this is called bystander intervention. But intervention becomes less likely to an extent that no single person will intervene from a crowd or group of observers when someone is in need of help. This is called bystander apathy.

Obedience refers to conditions where the individual is explicitly asked to do a task, and this instruction comes from an authority.

Conformity is a process where no explicit requirement is made to do a certain task. But peer influence and a need for acceptance pushes one to carry out the task.

Social loafing is also called Ringelmann's effect. It is seen in games such as tug-of-war and clapping hands after a performance. Larger a group is, lesser the individual performance as one thinks the others will do the job and bring the results. Minority influence usually involves a personal shift in private

opinion and is also a central component of identity politics.
Excerpted from Social Loafing, Including Definition and Examples. (n.d.). Retrieved from http://www.psychologyandsociety.com/socialloafing.html

The correct answer is: A man standing alone in a lonely road helped another person in trouble. → Bystander intervention, A man stole a bottle of water from a shop. He was sentenced for one month "so that all other offenders know the consequences of shop-lifting." → Obedience, An affable person becomes violent when he participates in a rally along with a number of charged-up individuals. → Conformity, During a committee meeting, some of the employees did not make much of an effort and had few suggestions. These employees had made a much greater effort on other tasks in which they worked alone. → Social loafing, A politician is giving a talk to persuade the public regarding his views about economic repression and the need for more borrowing to improve it. → Minority influence

Question **28**

Not answered

Marked out of 3.00

Societal Influence

Match each of the proponents below with the concept proposed from the given list.

Goffman Choose...

Mechanic Choose...

Parsons Choose...

Choose...
Illness behaviour
Handicap
Biopsychosocial model
Moral insanity
Role stripping
Impairment
Illness
Abnormal illness behaviour
Sick role
Institutional neurosis
Primary deviance

Explanation:

Irving Goffman wrote that in a psychiatric institution, the inpatient is stripped of many of his accustomed affirmations, satisfactions, and defences, and is subjected to a set of mortifying experiences: restriction of free movement, communal living, diffuse authority of a whole echelon of people, and so on. Thus, role stripping, or role dispossession, occurs.

David Mechanic undertook the study of illness behaviour, which he introduced in the late 1950's, with the intention to depict the large variability in reactions to symptoms and illness and to identify the various sociocultural, environmental, and psychological factors that affect such reactions. Illness behaviour refers to the varying ways individuals respond to bodily indications, how they monitor internal states, define and interpret symptoms, make attributions, take remedial actions, and utilise various forms of informal and formal care.

Talcott Parsons argued that being sick is a role, which means that certain expectations come with identifying oneself as sick. These expectations involve a balance of rights and obligations. A sick person is entitled to be relieved of normal work and family responsibilities, but is subject to seek medical treatment and comply with doctors' orders.

Ref: Capps D. The mortification of the self: Erving Goffman's analysis of the mental hospital. Pastoral psychology. 2016 Feb 1;65(1):103-26.

Mechanic D. Sociological dimensions of illness behavior. Social science & medicine. 1995 Nov 1;41(9):1207-16.

Frank AW. From sick role to practices of health and illness. Medical education. 2013 Jan;47(1):18-25.

The correct answer is: Goffman → Role stripping, Mechanic → Illness behaviour, Parsons → Sick role

Stigma

Match each of the descriptions below with the concepts from the given list

Marked out of 3.00

Choose...
Negotiated order
NIMBY stigma
Courtesy stigma
Enacted stigma
Stereotype
Status frustration
Felt stigma
Directed stigma
Positive discrimination

A 43-year-old woman applied for a secretarial job after two years of unemployment secondary to depression. At the job interview, she was asked very detailed questions about the Mental Health Act invoked during her hospitalization. — Choose...

A hospitalized patient in a female ward is allowed to go out on short breaks daily if she returns a urine sample for drug tests. — Choose...

A highly disabling fear of discrimination perceived by patients and carers. — Choose...

Explanation:

Scambler and Hopkins suggested that there are two facets of stigma: enacted stigma and felt stigma. Whereas enacted stigma refers to the perceived act of discrimination against individuals with a stigmatising condition, felt stigma refers to the individual's embarrassment and shame associated with the condition. This conceptualisation allows for a multifaceted assessment of stigma by including both behaviours towards the individual, and feelings of the individual.

In negotiated order theory developed by Strauss and colleagues, the individuals in an organisation play an active, self-conscious role in the shaping of the social order. Their day-to-day interactions, agreements, temporary refusals, and changing definitions of the situations at hand are of paramount importance. The negotiated order theory downplays the notion of organisations as fixed, rather rigid systems which are highly constrained by strict rules, regulations, goals, and hierarchical chains of command. Instead, it emphasises the fluid, continuously emerging qualities of the organisation, the changing web of interactions woven among its members, and it suggests that order is something at which the members of an organisation must constantly work.

Day R, Day JA. A review of the current state of negotiated order theory: An appreciation and a critique. Sociological Quarterly. 1977 Jan;18(1):126-42.

The correct answer is: A 43-year-old woman applied for a secretarial job after two years of unemployment secondary to depression. At the job interview, she was asked very detailed questions about the Mental Health Act invoked during her hospitalization. → Enacted stigma, A hospitalized patient in a female ward is allowed to go out on short breaks daily if she returns a urine sample for drug tests. → Negotiated order, A highly disabling fear of discrimination perceived by patients and carers. → Felt stigma

Effect of Culture

Match each of the descriptions below with the most appropriate effect of cultural processes from the given list.

A Malaysian man humiliated in public takes a weapon and kills people indiscriminately to prove his manhood. — Choose...

A 23-year-old woman is prone to a sudden onset of a transient dissociative attacks induced by startling. She is often provoked on social occasions and acts like a clown, providing social entertainment. — Choose...

At an international health convention, a health minister form one of the members nations argued that cultural permission to consume alcohol freely may increase the prevalence of drinking problems. — Choose...

Explanation: Culture substantially influences psychopathology (Tseng and Streltzer 1997). The various ways that culture contributes to psychopathology have been termed pathogenetic, pathoplastic, pathoelaborating, pathofacilitating, pathodiscriminating, and pathoreactive effects (Tseng 2001). Tseng argued that culture could have pathogenetic (i.e. culture is a direct causative factor in forming psychopathology) or pathoselective effect (i.e. culturally influenced behavioural selection resulting in the manifestation of specific psychopathologies e.g. family suicides in Japan or amok in Malaysia [case 1]) in many culture-bound disorders. It may be pathoplastic too (modelling of manifestations of psychopathology). The content of delusions, auditory hallucinations, obsessions, or phobias is subject to the environmental context in which the pathology is manifested. Culture may also be pathoelaborating (behaviour patterns get exaggerated to the extreme). This is well illustrated by the unique mental phenomenon of Latah (case 2), which is mainly observed in Malaysia, where the universal dissociative reaction to stress becomes exaggerated to the extreme through cultural reinforcement (Simon, 1996). Culture can also be either pathofacilitative (some conditions are more common in some cultures e.g. alcohol abuse) or pathoreactive (culture influences people's reactions to distress and illnesses).

The correct answer is: A Malaysian man humiliated in public takes a weapon and kills people indiscriminately to prove his manhood. → Pathoselective, A 23-year-old woman is prone to a sudden onset of a transient dissociative attacks induced by startling. She is often provoked on social occasions and acts like a clown, providing social entertainment. → Pathoelaborating, At an international health convention, a health minister form one of the members nations argued that cultural permission to consume alcohol freely may increase the prevalence of drinking problems. → Pathofacilitating

Medical Ethics and Principles

Identify one suitable principle applicable to each of the following description.

During the second world war, the Nazi medico-military programme prisoners were shot in order to study gunshot wounds. — Choose...

You decide that a patient who has previously developed renal impairment on lithium carbonate should not be treated with it for a second time due to the risk of developing the condition again. — Choose...

A general manager of a regional psychiatric service has had her budget significantly reduced. She has to choose to cut either a day hospital service or an early intervention service. — Choose...

A woman has a probable bone cancer discovered on a routine bone scan to detect osteoporosis. She is not informed about the suspected malignant tumour, but is followed up with serial bone scans every few months to see if it is growing. — Choose...

A 76-year-old man was diagnosed with Parkinson disease dementia. He is due to be treated with antidementia drugs. He has been offered a choice to choose oral tablets or transdermal patch. — Choose...

Choose...
Empiricism
Utilitarianism
Conscience
Autonomy
Beneficence
Paternalism
Non-maleficence
Balanced decision
Justice

Explanation: The unacceptable Nazi medical experiments can be considered as an instance of extreme utilitarianism. In Nazi medico-military programme, prisoners were shot to study gunshot wounds, the consequentialist argument being the greater good for more number of people in the future as a result of these experiments.

Non-maleficence is often the reason for avoid re-challenging with drugs causing adverse effects.

Justice is the primary ethical consideration in the area of health care resource allocation since justice is concerned with fairness or equity in distributing goods to people. Justice means ensuring that as far as

possible all sections of the community get their 'fair share' of those resources.

In certain terminal illnesses, questions often arise concerning how much truth to tell. When, if ever, is a physician justified in withholding information? Can too much information be harmful? These conflicts between benevolent paternalism on the part of the physician and an increasing interest on the part of the patient to preserve autonomy are not easily resolved.

Offering choices among medications is a way of respecting patient's autonomy.

The correct answer is: During the second world war, the Nazi medico-military programme prisoners were shot in order to study gunshot wounds. → Utilitarianism, You decide that a patient who has previously developed renal impairment on lithium carbonate should not be treated with it for a second time due to the risk of developing the condition again. → Non-maleficence, A general manager of a regional psychiatric service has had her budget significantly reduced. She has to choose to cut either a day hospital service or an early intervention service. → Justice, A woman has a probable bone cancer discovered on a routine bone scan to detect osteoporosis. She is not informed about the suspected malignant tumour, but is followed up with serial bone scans every few months to see if it is growing. → Paternalism, A 76-year-old man was diagnosed with Parkinson disease dementia. He is due to be treated with antidementia drugs. He has been offered a choice to choose oral tablets or transdermal patch. → Autonomy

Question **32**

Sternberg's Theory of Intelligence

Identify the correct cognitive faculties to match the three levels of abilities described by Sternberg's Triarchic Theory of Intelligence from the given list.

Analytical Abilities: Choose...

Creative Abilities: Choose...

Practical Abilities: Choose...

Choose...
Applying knowledge
Attention
Set-shifting
Discovery
Aspiration
Consciousness
Comparison
Motivation

Explanation:

The triarchic theory of intelligence was put forward by Sternberg, according to whom its three fundamental aspects are analytic, creative, and practical intelligence, only the first of which is measured by conventional IQ tests. Analytic problems require the problem-solver to analyse, evaluate, compare, contrast, judge, and so on; creative problems to create, invent, discover, imagine, and so on; and practical problems to apply, put into practice, use, implement, and so on.

Ref: Colman AM. Oxford Dictionary of Psychology, 4 th Edition. 2015.

The correct answer is: Analytical Abilities → Comparison, Creative Abilities → Discovery, Practical Abilities → Applying knowledge
